Stage Three is direct physical resistance. Direct physical resistance is the last resort and it should be avoided and delayed as long as possible and only invoked when all other options have been thoroughly exhausted. There are those who 'talk tough' and claim that they will resist when the time comes, but what they fail to realise is that if you are inactive during the first two Stages and save your efforts for the last resistance, then you will fail.

When the Nazis were moving from door to door, dragging people out of their homes in Germany, that was the time to fight back physically, but due to the lack of ideological resistance and civil disobedience leading up to that moment, even an armed uprising would have likely failed at that point. An armed uprising can only succeed if the people have established an attitude of active resistance. And active resistance is only possible after their minds have broken free from the mainstream propaganda. If you want to fight back, then it's now or never – you're not going to get another chance, and the stakes are far higher than they were in Nazi Germany.

If you want to know more about the present situation, then watch the very informative web video at <http://www.youtube.com/user/ThriveMovement>, which also shows what you can do to improve things.

Chapter 11: Other Devices and Theories

Nikola Tesla's Ionised-Air Electrical Generator.

Tesla also designed a device for picking up energy from the air. As far as I am aware, it was never patented and I have never seen a specification of its output. Perhaps it was one of Tesla's failures but personally, I doubt that. It might make a very interesting experiment so see what level of output can be achieved using it. The construction is shown here:

It is essentially, a rectangular cylinder which contains two spherical electrodes like a Wimshurst machine. The cylinder is positioned vertically, so that when the electrodes are powered up with high voltage to create spark discharges, the air inside the cylinder is heated which causes it to rise up the cylinder. The heated air is ionised, so a magnetic field generated by a surrounding electromagnet, causes the charged ions to move to opposite sides of the cylinder. Electrode plates positioned inside the cylinder, provide an electrical path for the excess positive and negative charges to flow together through the load - lighting, heating or motor circuits typically.

On the surface, this system would appear to be less than 100% efficient, in that the amount of power applied to the device to make it operate should be less than the amount of power drawn from it to drive useful loads. I am not sure that this is necessarily so. Firstly, the air already contains charged ions before this device starts to generate more. These naturally occurring ions gain in number when a thunderstorm is likely, even to the extent of giving many people a headache by their presence. These naturally occurring ions will be picked up by this device and without any input power needed to create them, they are capable of providing output power.

Also, the whole earth is immersed in the zero-point energy field. This is seething energy at the quantum level whose effects can be seen even at 'absolute zero'. This field is made of small random effects which

makes it hard to obtain useful energy directly from it. The field needs to be structured before energy can be drawn from it. One way to do this is to align the field with an event which causes coherent waves of energy to radiate outwards as a 'radiant energy' wave - something like the ripples caused on the surface of a pond of still water when a large stone is dropped vertically into the water. The ripple 'waves' move outwards from the 'event' until they reach the bank of the pond. If there was a generator attached to a float in the pond, it would be possible to pick up some energy from the ripples. The same can be done with 'radiant energy' waves if you can create them and know how to pick up energy from them.

Radiant energy waves can be formed by very short sharp uni-directional electrical pulses. Pulses less than one hundredth of a second are suitable for this. One way of creating pulses of that type is using a spark gap. In Tesla's device shown above, sparks are generated continuously. These sparks will generate radiant energy waves radiating out at right angles to the spark. Without a doubt, the vertical cylinder will have a mass of radiant energy shooting up it when it is being operated. This is in addition to the air ions which are being picked up. The only question is whether or not the electrode plate arrangement shown is capable of picking up any of this excess energy. Considering the metallic pickup device used by Edwin Gray to capture radiant energy as described below, it seems highly likely that some of that additional energy is, in fact, picked up and used to power the loads.

It should be noted that Tesla's device shown above, will generate UV radiation in the same way as any MIG or stick welder does, so care should be exercised to avoid looking at the arc or allowing the UV to shine on your skin, even if the skin is covered by clothing. You can get serious sunburn through thin clothing if it is subjected to strong UV radiation. Also, radio interference is likely to be generated by the arc, so screening should be provided during any tests. **WARNING:** Tesla accidentally discovered that electric spark discharges in air, ignite and burn atmospheric oxygen and nitrogen, producing 12,000,000 volt waves. The oxygen and nitrogen, both below atomic number 19 are thereby transmuted into alpha and beta charges (stripped helium nuclei with +2 charge each, and electrons with -1 charges each) by the powerful radiation produced, having a voltage potential of 12 Mev. This is almost three times the Mev level of gamma radiation emitted by radium, it may well be the reason why Tesla did not publicise the device shown above, and should you decide to experiment with it, please be aware of the potential hazard of this radiation.

A variation on the above device of Tesla's is given in the book "Physical Chemistry" by E. A. Moelwyn-Hughes, Pergamon Press, Oxford 1965, page 224. Rutherford and Geiger determined the fact that radium puts out alpha particles at the rate of 34,000,000,000 per second, each having two units of positive charge at 4.5 million electron-volts. This is a staggering amount of energy which ionises the air inside the housing and produces enough power to be capable of replacing the entire Four Corners power complex indefinitely.

The variation of Tesla's device shown above, supports the lead container with its gram of radium on a strap across the bottom of the housing. The radiation ionises the air and the magnetic field separates the charges and directs them to opposite sides of the housing, to be collected and used via the electrode plates. There

does not appear to be any reason why strong permanent magnets should not be used instead of the DC electromagnet shown.

Dr Harold Aspden's Electrical Power Generator Patent.

Scientists freely acknowledge that more than 80% of the matter and energy in the universe is "dark matter" and "dark energy" where "dark" only means that we cannot readily see that form of matter and energy. The highly respected British scientist Dr Harold Aspden, has been awarded a patent for a system to collect this energy directly. The patent, which is one of several similar patents included in this eBook, is reproduced here:

Patent GB2390941

21st January 2004

Inventor: Dr. Harold Aspden

ELECTRICAL POWER GENERATING APPARATUS

Abstract

An electric generating device includes two capacitors **1** and **2**, each having a pair of concentric electrodes and in-series connection to inductors **3** and **4**. Each capacitor has an electrode connected to a high voltage DC source **5** and another connected to a low-voltage or earth terminal **6**. An AC Power output may be produced from terminals between each capacitor and inductor or from a transformer where the inductor is the primary winding. Electricity production may be sustained by drawing energy from the vacuum medium surrounding the electrodes.

Field of the Invention

This invention relates to a new and non-conventional means for the generation of electrical power. The energy source is the quantum underworld of space, the aether medium of the vacuum state, long recognised for its ability to allow the storage of electric field energy by reacting as its intrinsic charge is displaced, a process understood by physicists by reference to the research findings of Clerk Maxwell.

Background of the Invention

The current state of the art of electrical power generation does not recognise the possibility of ultimately tapping energy from the aether. Physics is taught on the basis that energy cannot be created or destroyed, inasmuch as it is conserved in all physical processes, though it can be degraded in its usefulness, as by burning of hydrocarbons and conversion into heat which dissipates as by radiation into outer space. The aether as a source or as an absorber of energy is not deemed to serve any specific role in the physics of energy deployment, it having been dismissed from consideration by invoking the notion of 'field energy' without admitting the specific physical reality of something in space that accounts for the properties involved.

Theoretical physicists have, however come to suspect that space devoid of matter is nevertheless a seething sea of activity subject to sporadic energy fluctuations which can create electron-positron pairs that exist momentarily before decaying back into their quantum underworld. Yet those same physicists deny all possibility that this energy resource of space itself can be exploited to provide useful power on a scale large enough to rival the role played by atomic power plants and fossil fuel generating installations.

Curiously, they do subscribe to the belief that one day they may be able to generate power on a viable commercial scale from fusion reactors by processes replicating what they believe sustains the Sun's heat output as hydrogen is transmuted into different atomic forms. In contrast with this rather elusive objective, it having proved beyond reach even after half a century of effort, this invention is based on success in generating power by replicating, not the Sun's onward energy decay, but rather a process akin to that by which the Sun itself was created from energy drawn from the enveloping aether medium.

The invention to be described below has emerged from an in depth theoretical investigation into the properties of the aether and quite independently of any of the well known claims of published record which feature at the fringe of mainstream scientific literature. A recent and very well-presented account of what amounts to a century of relevant energy history is the book 'The Search for Free Energy' by Keith Tutt, published in 2001 by Simon Schuster (ISBN 0-684-86660-9). Here in this book is a comprehensive background of information concerning the energy devices of several researchers but the references to Nikola Tesla and T. Henry Moray are particularly pertinent to the subject of this invention and, though imposing a

limitation on what can be legitimately claimed by this patent application, they serve also as a basis for a very important lesson to those engaging in this field of invention.

The lesson is that it is not sufficient to build and demonstrate something that works, if you do not fully understand why what you have devised actually does work. This is especially the case here where one is claiming a source of energy hitherto unknown. The invention to be described below will, in its broadest sense, appear to be quite similar to what T. Henry Moray is said to have demonstrated in showing that substantial electrical power could seemingly be drawn from the aether using a simple wire antenna strung between two poles.

However, as will be seen, the antenna is not needed and the reason is that the energy source is not the radiant emission by some process involving radio wave propagation through the aether, but rather what can best be described as a phase-lock that couples the apparatus with the quantised motion of electric aether charge. There is a technique, to be described below, by which it is possible to exploit this phase-lock condition by setting up an energy oscillation involving an apparatus component and its enveloping aether, the result being that energy in an immediately useful electrical form is imported into the apparatus from that aether.

Brief Description of the Invention

According; to one aspect of the invention, an electric power delivery circuit comprises two capacitors, each having a pair of electrodes formed by a pair of metal cylinders having concentric axes, each capacitor having an associated inductor series-connected to it to form a capacitor-inductor unit, DC voltage excitation means connected to a parallel combination of the two capacitor-inductor units, whereby to apply between corresponding electrodes of the capacitors a DC bias voltage which primes them with electric charge, and power output terminals, one at each point of connection between a capacitor and its associated inductor, whereby to provide for an AC power output owing to oscillations of electric charge between the two capacitors at the resonant frequency of the capacitor-inductor units.

According to another aspect of the invention, an electric power-delivery circuit comprises two capacitors, each having a pair of electrodes formed by a pair of metal cylinders having concentric axes, each capacitor having an associated inductor series-connected to it to form a capacitor-inductor unit, DC voltage excitation means connected to a parallel combination of the two capacitor-inductor units, whereby to apply between corresponding electrodes of the capacitors, a DC bias voltage which primes them with electric charge, each inductor being the primary winding of an electrical transformer, the secondary winding of which serves to provide an AC power output owing to oscillations of electric charge between the two capacitors at the resonant frequency of the capacitor-inductor units.

According to a feature of the invention the capacitors have no intervening solid or liquid dielectric medium separating their concentric electrodes.

According to another feature of the invention, two inductors are coupled electromagnetically by having a common ferrite core and their primary windings are connected to their associated capacitors in the polarity configuration which assures that, in their mutually resonant state, electric charge is exchanged between the two capacitors.

According to yet another feature of the invention, the central axes of both cylindrical electrode capacitors are mutually parallel.

According to a further feature of the invention, an electrical power delivery system comprises a plurality of these electric power delivery circuits, where the central axes have different angular orientations as between the different circuits.

According to a still further feature of the invention, in such a power delivery system, the difference in angular orientation of the central axes is at least 60° .

Brief Description of the Drawings

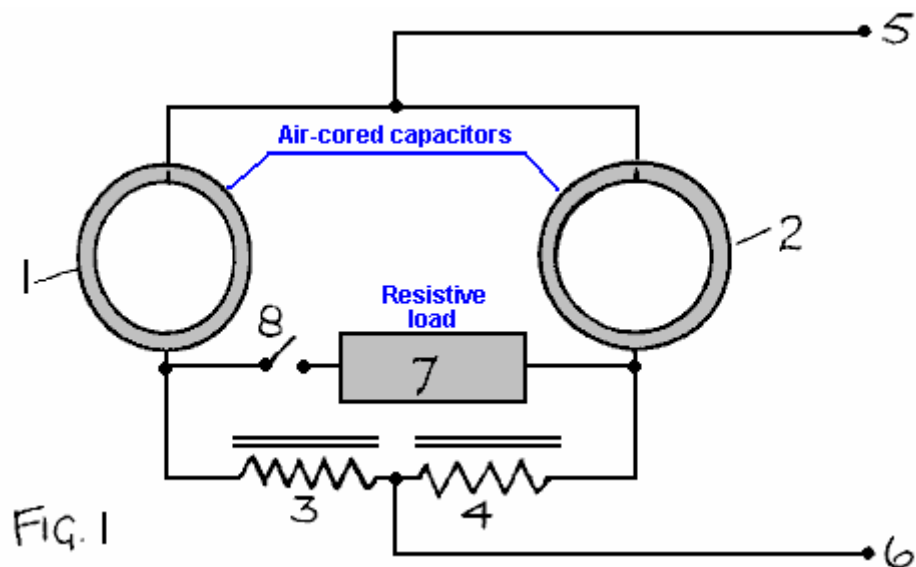

Fig.1 shows an electrical power generating circuit incorporating two concentric cylindrical capacitors having central axes which are parallel.

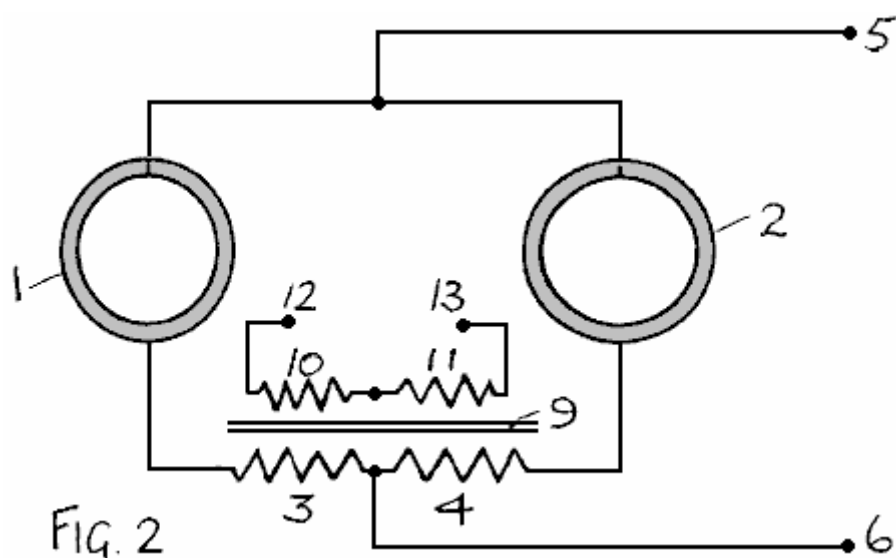

Fig.2 shows a modified version of the circuit of **Fig.1** with a transformer system providing the inductors and an output winding.

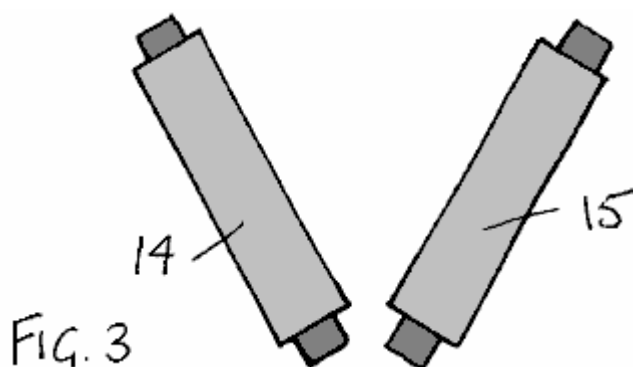

Fig.3 illustrates a mutually inclined capacitor system comprising two pairs of concentric cylindrical capacitors.

Detailed Description of the Invention

The invention draws energy from the aether. To understand why the invention works, one needs to understand the process by which the aether stores energy when an electric field is set up across the dielectric separating two capacitor plates. Moreover, one needs to understand the means by which the aether determines the quantum of action, specifically in the form of the Bohr magnetron and the unit of angular momentum linked to Planck's constant.

It is not sufficient to imagine that electric charge in the aether is displaced from a rest position in a background continuum of opposite charge polarity to which it is attracted by a restoring force. Indeed, one must consider such action to be superimposed on a system of charge which has an underlying jitter motion, a quantum theory theme associated with the German physicist Heisenberg (Zitter-bewegung, which has the dictionary meaning 'Circular fluctuation movement, of spin'). When these two factors are combined, and the constraint added of there being a phase-lock which keeps that jitter motion in synchronism as between the charges, one finds that the physical theory involved has some very interesting consequences.

One of these consequences is that a spherical or cylindrical volume of aether, if spinning bodily about a central axis, will acquire a magnetic moment and set up an electric field inside that sphere or cylinder that is directed radially with respect to the spin axis. A summary analysis is presented in the Appendix to this specification, being, in part a quotation from pages 31-33 of a booklet entitled 'The Theory of Gravitation' which the Applicant of this invention, Dr. Harold Aspden, authored in 1959 and duly published early in 1960.

The induction of electric charge by 'aether spin' was there shown to give a physical basis, both qualitative and quantitative, for the geomagnetic moment, the property of body Earth of setting up a magnetic field which created magnetic North and South poles at latitudes offset from the geographic poles, with the geomagnetic polar axis precessing slowly around the Earth's spin axis at a rate of several hundred years per revolution. By identifying its source as a rotation of a sphere of aether coextensive with body Earth, a volume of aether relative to which the Earth could have a component of motion even though the aether spin frequency is equal to that of the Earth, this axial tilt of some 17 degrees has a physical explanation. However, that aspect of the aether's role was not seen at the time as offering anything of promise technologically. The physics involved is nevertheless very relevant and directly pertinent to the experiments on which this invention is based, the findings of which would otherwise be quite baffling scientifically.

The applicant has, over the 40 or so years since the theory was first published, given a great deal of consideration to the theoretical implication that, just as aether spin can set up electric charge displacement inside coextensive matter, so the setting up of an electric field directed radially with respect to an s axis can induce aether spin about that axis and with it develop angular momentum. Indeed, in the author's onward publications on this subject, as, for example, 'Physics Unified' published in 1980 by Sabbeton Publications, P.O. Box 35, Southampton, England (ISBN 0 85056 0098), it is shown how the onset of the force of gravitation when a disordered aether consolidated into an orderly structured form caused protons to accrete more rapidly than electrons, owing to their higher mutual rate of gravitational acceleration. This created stars with all initial positive charge and the associated aether spin resulted in the stars acquiring their spin states and shedding matter which consolidated into planets which share the angular momentum so generated. The aether with its property of spin as related by its electric charge density according to the formula presented in the Appendix is therefore the key factor if we attempt to account for the creation of the stars which populate our universe.

That same formula, however, is equally valid if applied to the circumstance where a radial electric field is set up between the concentric cylindrical electrodes of a capacitor formed around a hollow dielectric cylinder. It tells us how fast the aether within that dielectric will spin. The related theoretical analysis shows that the quantum phase-lock feature of the aether imports from the external aether world an amount of energy equal to that supplied in setting up aether charge displacement, this imported energy being the dynamic energy corresponding to the acquired aether angular momentum. Guided by the argument concerning stellar creation one can see that this aether angular momentum can be transferred to matter and this process also has its energy transfer implications.

However, one can wonder what happens if, after setting up a radial electric field in that capacitor having concentric electrodes, the applied voltage is reduced, thereby withdrawing electric field energy from the capacitor. The imported energy present in kinetic energy form as a cylindrical shell of aether spins about the central axis of the capacitor will tend to sustain electric charge displacement. To conserve energy, since the

aether phase-lock cannot force the expulsion of energy by obliging the enveloping aether universe to keep in step, this energy can only be shed by augmenting that released electrostatically. In other words, the net result is that an up and down fluctuation of the electric charge condition of the capacitor must give rise to an electric energy output that is, for the lowest dielectric constant (the permittivity of the vacuum), double the input in each cycle of change. One can then envisage an oscillation escalating in energy content powered almost wholly by aether input before one taps into that source of power to draw off energy at a rate consistent with stable operation.

This is, of course, a bewildering prediction that no physicist could imagine as being at all possible and yet, given the relevance of the theoretical argument involved, as applied to the phenomenon of geomagnetism and stellar creation, which are supported by strong evidence in that book 'Physics Unified', once such a notion is conceived it surely has to be put to the test by experiment. This then, after decades of effort before this realisation has dawned, is the basis on which the Applicant has only now come to appreciate the amazing technological possibilities that lie before us and is asserting by this patent specification that energy can in fact be tapped from the aether on a commercially viable scale.

Given that aether theory indicates that the special form of capacitor described above will, if subject to an oscillatory charge condition, generate an excess of energy, a question to consider is why such a phenomenon has not manifested itself in bench-type experiments performed in numerous electrical laboratories over the past one hundred years. Ostensibly the implication is that the capacitor will exhibit a negative resistance if used with an inductor as a component in what would become a self-resonating circuit. The answer to this may be that if such a phenomenon has occurred it has passed unnoticed or been regarded as spurious or noise-related, being something connected with radio interference etc. Alternatively, and as a function of the size and scale of the apparatus, the effect may have lacked an exciting trigger needed to overcome an energy threshold set by such factors as circuit contact resistance or contact potentials as well as the basic resistance of the inductors which, with the capacitors, form the resonant circuit.

Note that, even for a capacitor of quite large physical dimensions, having regard to its accommodation on top of a laboratory bench, the actual capacitance is necessarily quite small. being of the order of a billionth of a farad. This means that a capacitor charge fluctuation of the order of a volt would only imply energy fluctuations that are of the order of a billionth of a joule per cycle. The situation is quite different if perchance a DC bias voltage of, say, 5,000 volts is applied to the capacitor. Then a small superimposed voltage fluctuation makes the related energy fluctuations very much larger with much greater prospect of an escalating self-resonance being triggered.

With this in mind the applicant perceived a possible prior art link with the experimental claims reported by Dr. Moray who, in 1929 is said (see pages 46-50 of the above-referenced recently-published book by Keith Tutt) to have powered six 100 watt light bulbs plus a standard 575 watt electric flat iron, merely by providing an earth connection and coupling an input lead to an overhead wire antenna. The apparatus involved had no other source of input power but included a special arrangement of capacitors and presumably some kind of high frequency inductor/transformer unit.

In spite of the attention given to the Moray demonstrations, it seems that the secrets involved in the design and construction of the apparatus remain unknown and so cannot feature in the prior art of published record. Nor, indeed, can the anecdotal evidence of Moray's efforts serve to show that the subject invention has been put to prior use. The technology as to how to replicate the Moray device, always assuming it did perform as claimed, has therefore to be rediscovered and, indeed, given that there is reference to his detectors incorporating some special substance which was referred to as 'Swedish stone', possibly the dielectric he used in his capacitor construction, there is a considerable mystery to unravel. More to the point, however, one is led to believe that Moray was implying that the energy he was tapping was radiant energy drawn from the aether, with that antenna featuring prominently because, without it being connected, the energy output fell to zero. However, as he surely may well himself have known, one just cannot draw power on such a scale from a simple overhead wire strung between two poles and so, without know how, he would have suspected that the energy inflow was coming into his capacitors via the action of that mystery substance he called 'Swedish Stone'.

The applicant here suggests that, based on an insight into the quantum workings of the aether medium as outlined above, the curious discovery demonstrated decades ago by Dr. Moray may have been attributable to setting up an oscillation in a resonant circuit including, a concentric cylindrical electrode capacitor which had a voltage bias of the order of a thousand and more volts fed from a connection to that overhead antenna but drawing no significant current from that antenna other than enough to prime his capacitor with charge

and stimulate a high frequency fluctuation which could initiate an escalating circuit oscillation tapping aether energy from the aether spin induced in the capacitor dielectric.

This is speculation, but it is sufficient to justify the Applicant's interest in constructing a capacitor and seeking to verify the assumptions just made. Notwithstanding, the reference alcove to Dr. Moray and the note below concerning Nikola Tesla, what it leads to is new invention by virtue of full disclosure of details of operation and manufacture of something hitherto unknown, the actual means by which to harness a source of energy latent in the aether medium and deemed by those familiar with state of the art knowledge to be beyond man's reach. Furthermore, there are supplementary inventive features of a special nature because of the way the subject invention exchanges energy between two capacitors and also because the optimisation of aether power output from the capacitors is found to be a function of the orientation of the capacitor axes relative to the cosmic background owing to the Earth's rotation.

It seems here appropriate to mention something described by Nikola Tesla in his U.S. Patent No. 685,958. This was filed on 21 March 1901 and granted on 5 November 1901. It was entitled: 'Apparatus for the Utilisation of Radiant Energy'. By installing two metal plates, one high above the ground and the other at ground level, with wires connecting the plates to separate electrodes of a capacitor, it was stated that the capacitor became charged to a very high potential, the energy input being that radiated to Earth from outer space. This may well have motivated the efforts of T. Henry Moray but, so far as this Applicant's invention is concerned, no such input from overhead components is necessary as a quite different energy source is at work, namely the zero-point vacuum energy activity of our quantum underworld.

Referring now to **Fig.1**, two capacitors 1, 2 formed by concentric cylindrical metal electrodes and having their central axes parallel, form part of a resonant circuit combination by each being series-connected to an inductor 3, 4 having a ferrite core. Their inner electrodes are connected to a high-voltage DC source 5 and their outer electrodes are separately connected through their corresponding inductors to a low-voltage or earth terminal 6. A resistive load device 7 is connected via switch 8 between the junction points of the capacitors and inductors.

In operation, owing to spurious electrical signals induced in the inductors, or to an imposed electrical stimulus provided by means not shown, the priming electric charge of the two capacitors will develop oscillations as charge is exchanged between the two capacitors. There is energy inflow owing to the quantum coupling of electric charge displaced between the concentric electrodes of each capacitor and the quantum activity of the underworld of the enveloping aether. This affords an electrical energy output which is supplied upon closure of switch 8.

Referring to **Fig.2**, the inductors **3, 4** are shown to have a common ferrite core **9** and to have secondary windings **10,11**, which, by transformer action, can supply electrical power output between terminals **12** and **13**.

The apparatus of **Fig.1** and **Fig.2** will, when viewed in side elevation, appear as having a capacitor form with an outer cylindrical electrode within which there is a slightly elongated inner cylindrical electrode, to facilitate the high-voltage connection to that inner electrode. **Fig.3** shows, in very simple diagrammatic form, two such arrangements **14, 15**, with the central axes of the two pairs of capacitors mutually inclined. There may, however, be three or more such pairs of capacitors, each pair constituting a circuit such as is depicted in **Fig.1** or **Fig.2**.

The reason for configuring multiple capacitor systems, each with its own power output, in a combined manner with the outputs merged to supply an overall energy producing system is that the aether energy output of each capacitor unit is a function of axis orientation. This is because the quantum activity of the aether has its own preferred axis and, as the Earth rotates there is variation of the relative axial orientation in a daily cycle. Also, one needs to cater for systems applying, this invention in a mobile application, which also implies change of orientation and by having; the mutually inclined capacitor axis configurations one can be assured that the potential power output avoids the null situation that can occur if the capacitor axes of a stand-alone unit of **Fig.1** or **Fig.2** were to be at right angles to the aether quantum spin axis.

The capacitor electrodes can be of thin metal sheet foam and so of light weight and preferably are not spaced apart by any dielectric medium, whether liquid or solid. They need to be held apart by a simple insulating frame structure. The reason is, that the only dielectric medium that is operative in the functioning of the invention is the vacuum medium and to have a normal dielectric present implies more capacitance and so extra current oscillation without extra energy gain per cycle of oscillation. The key factor assuring operation is the need for circuit resistance to be low compared with capacitance that is solely attributable to the vacuum medium combined with the high voltage priming which greatly enhances the power output to weight factor.

The two capacitors of a pair are preferably of identical capacitance and structure, as are the inductors, so that the oscillation period of the two resonant sectors of the circuit is the same. The common ferrite core feature of the **Fig.2** configuration assists in this role.

The apparatus will normally be designed to operate at a capacitor frequency of the order of 100 KHz or more, and a voltage of 10,000 V or higher, and so the transformer output of **Fig.2** will be preferable with voltage duly adjusted to suit the application. The high frequency AC so produced can then be converted as needed by using the appropriate technology of known form.

Appendix

Extract from pp. 30-31 of 'The Theory of Gravitation', 1960 printed publication by the Applicant. Note that the earlier pages explained that the aether comprises a system of electric particles in a cubic crystal-like distribution set in a uniform background continuum of opposite charge polarity, the particle system and the continuum both sharing a common circular orbital motion of radius **r** and the relative velocity between the particles and continuum being the speed of light.

The Effect of Aether Rotation

Consider what happens when a large volume of the aether is rotating bodily. The continuum and particle system rotate together. There will be no resultant magnetic moment unless the particle distribution is disturbed. An evident disturbance is the centrifugal effect arising from aether rotation, but for the angular velocities of magnitude found in the solar system this effect is of negligible consequence. A much more important effect arises from the synchronising interaction between particles in the rotating volume. This requires that the particles shall move about their neutral points at the same angular velocity. Thus if a particle is to have a velocity component **V** directed in the plane of its orbit, whilst retaining a mean velocity **C/2**, its speed along its orbit must be of the form $\mathbf{C} / 2 + \mathbf{V} \cos(\mathbf{P})$, where **P** is the angle subtended by a line joining the particle and the centre of its orbit relative to a fixed reference datum in the inertial frame. To satisfy the above requirement the centre of the orbit cannot be the neutral point. Evidently the particle is distant from this neutral point by $\mathbf{r} + (2 \mathbf{V} \mathbf{r} / \mathbf{C}) \cos(\mathbf{P})$. As **V** is much less than **C** the effect of this is that the particle is moving around a circular orbit whose centre has been displaced a distance $2 \mathbf{V} \mathbf{r} / \mathbf{C}$ perpendicular to **V** in the plane of the orbit. If **V** is much less than $\mathbf{w} \times \cos(\mathbf{A})$, where **w** is the angular velocity at which the aether rotates, **x** is the distance of the aether particle from the axis of rotation, and **A** is the angle of tilt of the axis to the common axial direction of the aether particle system, this displacement distance is $2 (\mathbf{w} \times \mathbf{r} / \mathbf{C}) \cos(\mathbf{A})$. Consider a disc-like section of the rotating aether of radius **x** and unit thickness. Then, the effective charge displacement arising from the effective physical displacement of the particles is $2 \pi \mathbf{x} \mathbf{s} (2 \mathbf{w} \times \mathbf{r} / \mathbf{C}) \cos(\mathbf{A})$. The disc has acquired a uniform charge density of $4(\mathbf{w} \mathbf{r} \mathbf{s} / \mathbf{C}) \cos(\mathbf{A})$ esu/cc. The polarity of this charge depends upon the direction of rotation of the aether.

When evaluated from the aether data already presented, the charge density is found to be: $4.781 \mathbf{w} \cos(\mathbf{A})$ esu/cc. This charge density represents a charge component which rotates with the aether.

Calculation of the Geomagnetic Moment

For Earth, **w** is 7.26×10^{-5} rad/sec and **A** is 23.5° . Thus the Earth's charge density is, from the above expression, 0.000319 esu/cc. The rotation of this charge gives rise to a magnetic moment of:

$(0.000319)(4 \pi / 15) \mathbf{w} \mathbf{R}^5 / \mathbf{C}$ where **R** is here the radius of the Earth's aether.

If **R** is greater than the Earth's radius (6.378×10^8 cm) by a small factor **k**, the Earth's theoretical magnetic moment becomes $(1 + 5\mathbf{k}) 6.8 \times 10^{25}$ emu. This may be compared with the measured value of the Earth's magnetic moment of 8.06×10^{25} emu.

An upper limit of 0.035 is imposed on **k** suggesting the Earth's aether terminates at a mean height of about 140 miles above the Earth's surface. This suggests that the ionosphere may be a phenomenon arising at the aether boundary.

Claims

1 An electric power delivery circuit comprising two capacitors each having a pair of electrodes formed by a pair of metal cylinders having concentric axes, each capacitor having an associated inductor series-connected to it to form a capacitor-inductor unit, DC voltage excitation means connected to a parallel

combination of the two capacitor-inductor units, whereby to apply between corresponding electrodes of the capacitors, a DC bias voltage which primes them with electric charge, and power output terminals, one at each point of connection between a capacitor and its associated inductor, whereby to provide for an AC power output owing to oscillations of electric charge between the two capacitors at the resonant frequency of the capacitor-inductor units.

- 2 An electric power delivery circuit comprising two capacitors, each having a pair of electrodes formed by a pair of metal cylinders having concentric axes, each capacitor having an associated inductor series-connected to it to form a capacitor-inductor unit, DC voltage excitation means connected to a parallel combination of the two capacitor-inductor units, whereby to apply between corresponding electrodes of the capacitors a DC bias voltage which primes them with electric charge, each inductor being the primary winding of an electrical transformer, the secondary winding of which, serves to provide an AC power output owing to oscillations of electric charge between the two capacitors at the resonant frequency of the capacitor-inductor units.
- 3 An electric power delivery circuit according to Claim 1 or 2, wherein the capacitors have no intervening solid dielectric medium separating their concentric electrodes.
- 4 An electric power delivery circuit according to Claim 1 or 2, wherein the capacitors have no intervening liquid dielectric medium separating their concentric electrodes.
- 5 An electric power delivery circuit according to Claim 1 or 2, wherein the two inductors are coupled electromagnetically by having a common ferrite core and their primary windings are connected to their associated capacitors in the polarity configuration which assures that, in their mutually resonant state, electric charge is exchanged between the two capacitors.
- 6 An electric power delivery circuit according to Claim 1 or 2, wherein the central axes of both cylindrical electrode capacitors are mutually parallel.
- 7 An electric power delivery system comprising a plurality of electric power delivery circuits according to Claim 6, wherein the central axes have different angular orientations as between the different circuits.
- 8 An electric power delivery system according to Claim 7, wherein the difference in angular orientation of the central axes is at least 60° .

Comments by Dr Aspden on 19th March 2006:

OUR ENERGY FUTURE

A Message of Vital Importance

The world needs a new source of energy, one that is not an exhaustible commodity subject to power-play as between nations. Yes, one can dream and then awake to say this is impossible, but I urge those with the necessary skills to heed what I have to say in my three messages below.

First, however, let me introduce myself. My name is Dr. Harold Aspden. I am retired and elderly but have had a lifelong scientific interest in fundamental physics relevant to the energy theme. My 6-year university education in U.K. was at Manchester University and Cambridge University (Trinity College). My 33-year working career in U.K. comprised 9 years with English Electric and 24 years with IBM. Though having high technical qualifications (see below), being interested in the specialised field of protecting inventions pertaining to electrical engineering, I became a Chartered Patent Agent and later a European Patent Attorney. My last 19 years with IBM were spent as Director of IBM's European Patent Operations. This was followed, in my early retirement, by 9 years as a Visiting Senior Research Fellow at Southampton University and thereafter my scientific interest has been a private pursuit evidenced by my writings as on this and my related websites. My formal qualifications are: B.Sc., Ph.D., C.Eng., F.I.E.E., F.I.Mech.E., C.Phys., M. Inst.P., C. Sci., Wh.Sc.

Message No. 1: Physicists have come to recognise that there exists a quantum underworld alive with energy and permeating all space. However, their related research aims merely at probing experimentally the spectrum of elementary particles that have a transient existence as a product of that energy activity. The reward they seek is recognition should new particles be discovered and, by their properties, reveal

connections with other particles that help in formulating a new theory or verifying an existing theory. Sadly, they do not see that quantum underworld as a potential source of energy that we can harness. Nor have they understood how most of the energy shed in creating matter formed the elementary particle which bears the name proton and which, together with the electron, constitutes the hydrogen atom.

There is also a secret they have yet to fathom. It is the effect of creating a radial electric field centred on electrical charge around which that quantum underworld can develop a state of spin that causes it to shed energy. In the presence of a radial electric field set up by an electrically charged body, whatever constitutes that quantum underworld that permeates all space shares a motion like that of sequence dancers who keep in step with one another as they move around the dance floor, a synchronous motion, which, in the presence of that radial electric field can only be held if a secondary motion develops around an axis centred in that radial field.

How else could the Sun spinning about its own axis have come into existence? Here we have gravity attracting hydrogen atoms and pulling them so closely together that ionisation occurs, meaning freeing some electrons from their proton bonding, and so, because the mass of a proton is very much greater than that of the electron, creating a Sun having a body that is positively charged sitting within an outer shell of negative electron charge. Two free protons experience a mutual rate of gravitational acceleration that is 1836 times that experienced by the interaction of two electrons. The body of the Sun, therefore, has a uniform mass density and a uniform positive charge density enclosed within a compensating negative charge at its surface. This is because gravitational compaction forces balance the expansion forces attributable to electrostatic repulsion. It further means the presence of a radial electric field within the body of the Sun and, in turn, owing to the effect of this field on the space medium of the quantum underworld, this induces a state of spin accompanied by release of energy from that medium to feed the kinetic energy of that spin.

In depth analysis of the physics involved, meaning the effect of the resulting radial electric field on that quantum underworld, then allows one to calculate the resulting rate of spin and thereby understand how the solar system was created.

So, if the reader is a physicist, here is the way forward and full guidance on this is to be found on my parallel website www.aspdn.org or in a new book of mine entitled Creation - The Physical Truth, that will be published in the near future. However, if the reader is not a physicist but has the technological aptitudes of the university-trained electrical engineer then it is Message No. 2 below that warrants attention.

Message No. 2: If it were possible to generate electrical energy by tapping an omnipresent medium it is surely to be expected that the occasional natural phenomenon might already have hinted at this possibility. Consider, therefore, the thunderball, a glowing spherical object sometimes seen, especially following a lightning storm. It appears aethereal in the sense that it can move unimpeded through matter, yet remains an enigma, an unsolved mystery of record in the annals of science. Lightning strokes are high current discharges which, as electrical engineers well know, can develop a 'pinch effect' squeezing the electron-carried current into a filamentary flow within a cylindrical channel of positively charged air. That implies a radial electric field, a pulsating radial electrical field if the discharge surges, a sure recipe for something to happen that could form a miniature Sun, the thunderball. So when we look at a thunderball we are looking at a natural phenomenon that has drawn energy from that quantum underworld of space, energy which is then dissipated, but energy shed by a process we can surely harness, once we understand the physics involved.

Scientists lacking the necessary imagination do not seek to understand how the thunderball is created and so they seldom write about it. So here we have something to think about. It is Nature's message telling us: "Produce a radial electric field, one that pulsates, and you can develop a spin that taps energy from the quantum underworld of space." As engineers, however, we need to be practical and, if possible, we should avoid trying to replicate a phenomenon that involves powerful electric discharges, if there are better ways in which to proceed.

So now I come to my primary theme in this Message No. 2. It is a brief survey of a few of the claims of record that have declared a mysterious energy gain and have features which I see as relevant to what has been said above. In particular I draw attention to the research findings of four different pioneers in what has come to be termed 'The Search for Free Energy', this being the title of a really excellent book by Keith Tutt, published by Simon & Schuster in 2001. Three of these are described in considerable detail in that work. I now ask you to keep in mind my reference to a radial electric field as I mention each of them below and do realise that electrical structures of cylindrical form are a key feature.

Nikola Tesla is famous for his research concerning electromagnetic induction and high voltage solenoidal transformer apparatus (Tesla coils) and he is said to have demonstrated an automobile which derived its

power by tapping energy from space. He did not disclose its design details and died leaving us with a mystery. Tesla coils comprise large solenoidal windings concentrically mounted and operate with high voltage pulsations between their cylindrical forms which must produce a pulsating radial electric field between those windings. So, although electromagnetic induction effects are the primary focus of attention, there is here scope for the electrical action described in Message No. 1 above. Tesla may well have stumbled experimentally upon a way of tapping energy from space, but without understanding the true underlying physical process.

Dr. Henry Moray, a pioneer of the 1920-1930 era, demonstrated something which merely needed a kind of antenna, a wire connected from tree tops to earth via electrical apparatus in the boot (trunk) of his automobile. It is said that the latter included several capacitors and that a kilowatt level of power was generated. In this case the automobile merely carried the test apparatus for demonstration at a location remote from a built-up area and any electrical power line interference. No doubt Moray was seeking to follow in Tesla's footsteps by drawing energy from the Earth's electric field, known to be measured in hundreds of volts per metre. It is likely that those capacitors were of Leyden jar type configuration, that is cylindrical in structural form, and that the wire linked to tree tops tapped charge at a kilovolt voltage level. However, the output power claimed could surely not have come from that source. Therefore one must assume that Moray used that treetop voltage input merely to prime the voltage across his capacitor electrodes, whilst incorporating some special feature in the operation of his electrical circuit that gave access to the energy of the quantum underworld. Capacitors having concentric electrodes of cylindrical form will, when charged electrically, have a radial electric field in the space between the electrodes. Several capacitors coupled together could give rise to oscillations of charge as between the capacitors and so lead to a pulsating radial electric field. Yet though demonstrating as possible something that should not be possible, a mysterious inflow of energy able to illuminate several light bulbs, Moray could surely not have understood the true physical process that was feeding energy into his apparatus. Again I see this as relevant to what is stated in Message No. 1.

Stan Meyer demonstrated apparatus that included sets of concentric tubular electrodes enclosed in a cylindrical container filled with water, the electrodes being fed by high voltage (5 KV) pulses. Combustible gas was generated, a mixture of hydrogen and oxygen, the burning of which generated far more heat than could be accounted for by the electrical energy input. Energy was being tapped as if from nowhere unless the source was the ambient medium of space itself. Here there was a pulsating radial electric field and electric charge oscillating between different components in Meyer's apparatus. Meyer did not offer any useful explanation as to the physical process underlying what he could demonstrate but persisted in conveying the message that the invention was wonderful and talking about a multiplicity of applications such as powering automobiles, ships etc. This is the project not mentioned in Keith Tutt's book. As for the Tesla and Moray projects Meyer's research was a U.S. based activity. It did, however, attract the interest of a British Admiral, Admiral Tony Griffin who was concerned with the impact of new technology upon the marine industries. Griffin witnessed Meyer's demonstrations and was interested in its development. Indeed an article on the subject mentioning Admiral Griffin and entitled 'Free Energy for Ever' was published in the January 1991 issue of the U.K. magazine *Wireless World*. The importance of the article was evident from the fact that the Editor of that magazine was the author.

Paul Baumann, a member of a Christian community in a isolated valley high in the Swiss Alps has constructed working free energy devices which have been demonstrated to visitors. The first working prototype was relatively small and included a pair of glass Leyden jars, concentric capacitors. Keith Tutt in his book devotes 30 pages to this subject. The high voltage needed to prime the capacitor operation was generated by a Wimshurst machine driven by the electric power generated. The community has, however, kept design details secret. In spite of such information as is available the underlying physical process governing its operation remains a mystery. Yet I can but feel confident that what I say in my Message No. 1 provides the answer.

Message No. 3: My Message No. 1 has drawn attention to the physical process by which the vast amount of energy needed to create the Sun was extracted from the quantum underworld that permeates all space. My Message No. 2 has drawn attention to the reported efforts of just some of the several energy research pioneers who actually demonstrated apparatus that, contrary to accepted scientific principles, drew energy from a mystery source. My Message No. 3, based on recognising the common physical feature can but be the suggestion that technology for generating our power needs from the hidden underworld of space has to be possible. Accordingly, I will now outline what I see as the basis on which to build the ultimate power generating device that harnesses the physical principles presented in Message No. 1.

Being 78 years of age and no longer having access to university research laboratory facilities, I can but leave it to others to take note and, hopefully, prove me right. If proved right then the world will benefit and the

impending energy crisis will be avoided. Hopefully also, the scientific community might then be willing to accept my claim as to how the quantum underworld deploys its energy into proton creation and is active in producing the phenomenon of gravitation. I know of no other theory that has been able to derive theoretically the value 1836.152 of the proton/electron mass ratio. I would like to see that recognised as my contribution to man's knowledge.

Consider a capacitor formed by a pair of concentric cylindrical electrodes, something many of us remember from the school physics laboratory, the Leyden jar. However, the capacitor structure I have in mind is very much larger and has to be operated at a quite high voltage. When that voltage is applied between the electrodes electric charge is displaced in the underlying vacuum medium located between those electrodes. A commensurate amount of electric charge is thereby held in place on those electrodes, a negative polarity charge on one and a positive polarity charge on the other. Given my claim that this is accompanied by 'vacuum spin', aether rotation, which has imported an equal amount of energy owing to a quantum phase-lock as between the charge of the vacuum medium, we have the energy gain we seek to exploit.

The problem, however, is that, with this simple capacitor configuration, the only control parameter available is the reduction of the voltage between the electrodes. This will shed energy within the circuit of the apparatus used, the outflow of electric charge at the voltage difference merely delivering energy equal to that originally supplied by our voltage source. The added energy imported from space is merely dispersed by the 'vacuum spin' slowing down but expanding beyond the bounds of the capacitor electrodes as it conserves its angular momentum. The energy imported from the quantum underworld of space has no way of enhancing the energy output of the capacitor circuit and so is left to dissipate itself and eventually be reabsorbed by that quantum underworld that pervades all space.

However, now consider a concentric electrode capacitor having a third cylindrical electrode intermediate the inner and outer electrodes. Here we have a control parameter other than the voltage between the outermost and innermost electrodes, because we can wonder about the voltage of the central electrode whilst retaining the other voltage difference at a constant high level. In fact, by keeping the latter voltage difference constant but varying the voltage of the intermediate electrode we can decrease the capacitor energy of one half of the overall capacitor as that of the other half decreases. The imported energy shed by one half of the overall capacitor can then contribute to the action that energises the other half and thereby induce oscillations from which energy can be extracted and deployed as a power source.

One needs two such capacitors having their central electrodes coupled through a load circuit in order to capture the 'free energy' inflow and get it to do useful work rather than being dissipated. An inductance in the coupling circuit can determine the oscillation frequency and, since the energy inflow increases with frequency, this should no doubt be well into the kilocycle region. The figure below is a simple schematic diagram of the electrical apparatus that I have in mind.

So my Message No. 3 is what I may describe as a 'thought experiment', one that I cannot verify myself, owing to my age and lack of facilities. I therefore can but record my thoughts and hope that others will prove me right and not wrong.

The capacitors depicted in the figure should have their electrodes spaced so that the capacitance C as between their central and outermost electrodes is the same as the capacitance C between their central and innermost electrodes. Suppose that the outermost electrodes are maintained at a voltage of 20,000V relative

to the innermost electrodes. This means that the two central electrodes will be at an intermediate voltage which we expect to be 10,000V in the absence of oscillations. However, as with any ever-active electrical system, there will be minor voltage fluctuations affecting the central electrodes. So we may ask what happens if the voltage of the central electrode of capacitor A decreases owing to electric charge being shed by the inner capacitance C but gained by the outer capacitance C. Think about that for a moment. You will see that it implies reciprocal action in the opposite sense by capacitor B, as current flows from A to B via the central inductor coupling. Yet no net current flows from the 20,000V power source.

Now, of course, common sense backed by our scientific training assures us that this system can but keep its equilibrium without those minor voltage fluctuations building up in some way. Yet, if we heed Message No. 1 and keep in mind Message No. 2, there is a question we must ask. If current does flow through that central link between A and B, one half of A and one half of B both shed energy and so release the imported 'vacuum spin' energy, if such is present. This occurs as other halves of A and B have to gain energy and as angular momentum of the imported 'spin energy' spreads into the other sections of the capacitors. The question then is: "Does that imported energy escape, as it does for the two-electrode capacitor configuration, or might it be retained and so augment the action?"

I submit the answer can only be provided by actual experiment. If the energy does escape then there is nothing further to discuss. However, if some of that energy is captured then we can expect an escalation of oscillations in that inductive link and so can then say that a new source of energy has been discovered. Those oscillations will be a function of the capacitance C and the inductance of the load circuit. Given a high frequency and a high voltage a significant level of power per unit volume of capacitor structure will be produced. If power output at a level commensurate with the claims of Tesla, Moray, Meyer and Baumann results the world's energy future is then assured. A pollution-free energy resource powered by the quantum underworld of space will be at hand wherever we are on body Earth.

The Design of Paulo and Alexandra Correa.

Paulo & Alexandra Correa have discovered a way of converting Tesla's longitudinal waves into ordinary electrical power. They have made US Patent Application 2006/0,082,334 entitled "Energy Conversion Systems" in which they show various ways of achieving this energy-type conversion.

Their techniques range from applying the longitudinal wave energy coming from a Tesla Coil directly to two capacitors via diode rectification and the voltages generated are related directly to actual ground earth potential:

The patent application forms part of this set of documents so the full details can be examined. A theory of operation is presented based on their many experiments and observations, and the practical form of one of their conversion devices is:

Where the active pick-up plates **R** and **T** are encased in a cylinder and are provided with a cone shape to assist the procedure. The patent application contains a good deal of information and is worth reading.

Professor Konstantin Meyl.

Another key person in the advancement of current theory and analysis is Professor Konstantin Meyl who has described how field vortices form scalar waves. He has described how electromagnetic waves (transverse waves) and scalar waves (longitudinal waves) both should be represented in wave equations. For comparison, transverse EM waves are best used for broadcast transmissions like television, while longitudinal scalar waves are better for one-to-one communication systems like cell phones.

Konstantin Meyl

He also presented the theory that neutrinos are scalar waves moving faster than the speed of light. When moving at the speed of light, they are photons. When a neutrino is slowed to below the speed of light, it becomes an electron. Neutrinos can oscillate between e^- and e^+ . Fusion involves e^- , and a lightning flash involves e^+ . Energy in a vortex acts as a frequency converter. The measurable mixture of frequencies is called noise.

Dr. Meyl has pointed out that Tesla measured the resonance of the Earth at 12 Hz. The Schumann resonance of the Earth is 7.8 Hz. Meyl shows how one can calculate the scalar wave of the Earth to be 1.54 times the speed of light. He has developed a model which ties the expansion of the earth to be the result of the earth's absorption of neutrino energy. The ramifications of this model are that neutrino energy can be tapped. He took this to the next step and postulated that Zero Point Energy is neutrino power – energy from the field; available at any time, and present everywhere. To show the place of neutrinos in conventional science, Meyl noted that the 2002 Nobel Physics prize was in regards to work on neutrinos. The English-language version of Dr. Meyl's web site is at <http://www.meyl.eu>.

Nikola Tesla's Magnetohydrodynamic Propulsion Drive.

Tesla performed an experiment in which he applied high-voltage high-frequency alternating current to a pair of parallel metal plates. He found that the 'space' between the plates became what he described as "solid-

state" exhibiting the attributes of mass, inertia and momentum. That is, the area transformed into a state against which a mechanical push could be exerted. This implied that, using this technique, it should be possible to produce a spaceship drive anywhere in space, if the mechanism for thrusting against the 'solid-state' space could be determined. Further experiments convinced Tesla that powerful electromagnetic waves could be used to push against (and pull against) what appears to be 'empty space'. The drive principle is based on the Hall-effect used in semiconductor magnetic sensors, and is called the magnetohydrodynamic ("MHD") effect. This might be illustrated like this:

Here, a box is constructed with two metal plates forming opposite sides and two insulating plates holding them in position and surrounding an area of 'space'. High-frequency, high-voltage alternating current is applied to the metal plates and this creates an electric field "E" acting between the plates as shown in black. A magnetic field "B" is generated by the electrical field. The magnetic field acts at right-angles to the electric field, as shown in blue. These two fields produce a propulsion thrust "F" shown in red in the diagram. This propulsion force is not produced by ejecting any matter out of the box, instead, it is produced by a reaction against the 'solid-state' condition of space-time caused by the high-frequency electromagnetic pulsing of that area of space. This is enormously more effective than a jet engine. The thrust increases with the fourth power of the frequency, so if you double the frequency, the effect is sixteen times greater.

To put this into perspective, consider the force being applied against gravity to lift an object into the air. The force pulling the object downwards is gravity and its strength is given by:

Gravitational force:

$$F = g \times M \times m / r^2$$

where

g is the gravitational constant ($6.672 \times 10^{-8} \text{ cm}^3 \text{ g}^{-1} \text{ s}^{-2}$)

M is the mass of the first body

m is the mass of the second body and

r is distance between the two centres of mass

The lifting force is given by:

Lorentz Force: Force on an object = Electric force + Magnetic force

$$\mathbf{F} = q \times \mathbf{E} + q \times \mathbf{v} \times \mathbf{B}$$

where

q is the charge on the object,

\mathbf{B} is the magnetic field,

\mathbf{v} is the velocity of the object and

\mathbf{E} is the electric field

How do these forces compare? Well, the electromagnetic force is stronger than the gravitational force by a factor of about 2,200,000,000,000,000,000,000,000,000,000,000 times. That number (2.2×10^{39}) is too big for anybody to really visualise, so let me put it another way.

If the amount of energy used to mechanically lift an object a distance of one hundredth of an inch (one quarter of a millimetre) off the ground, were used as an electromagnetic lifting force, then that amount of energy would lift the object more than 3,472,222,000,000,000,000,000 miles off the ground, or in metric units, more than 5,588,001,700,000,000,000,000 kilometres off the ground. This kind of drive is an entirely different kind of animal. This Hall-effect type of drive if used in a spaceship would require only a very small amount of input power to drive the ship at great speeds and over great distances.

As the device shown above operates directly on the space-time field which penetrates all matter, there would appear to be no reason why it should not be used to drive a conventional vehicle by positioning it in a horizontal position rather than the vertical position shown in the diagram. Throttle operation could be by very slight adjustment to the frequency of the AC pulses applied to the metal plates. However, Bill Lyne indicates that horizontal movement is better achieved by producing Tesla's very short, high-voltage high-frequency DC pulses at the front of the vehicle while at the same time generating very high-voltage high-frequency AC waves at the back of the vehicle. This style of drive is said to pull the vehicle along rather than push it along.

The **Unified Field Theory** is being searched for by scientists who want to come up with a theory which encompasses the force of gravity with the electromagnetic force. In my opinion, they would have more chance of success in trying to find a needle in a haystack which does not contain a needle since when the entire haystack has been disassembled, it becomes clear that there never was a needle in it. In my opinion, there is no such thing as a "force of gravity", in fact, there is no such thing as gravity. Find that hard to believe? Well, let me explain.

If when standing, you hold an object a waist level and let it go, it "falls" and lands near your feet. Yes agreed, and yet I suggest that there is no such thing as gravity. If you suspend a pendulum close to a mountain, the pendulum does not hang down vertically but moves slightly towards the mountain. This is said to be because the mountain attracts the pendulum. Sorry Chief, but I suggest that it just ain't true and the mountain does **not** attract the pendulum. The Moon orbits around the Earth which requires a continuous acceleration inwards towards the Earth and this is said to be caused by the attraction of gravity pulling the two bodies of matter together. Well, yes the Moon does orbit the Earth but not because of "the force of gravity".

The reason why "the force of gravity" is so tiny compared to electromagnetism is because there is no such force at all. Yes, indeed, all of the observed phenomena which are supposed to be gravitational, do exist exactly as seen, but I suggest that there is no such thing as "the force of gravity" and the Unified Field Theory is not needed. Let me explain:

The Zero-Point Energy field exists everywhere in the universe and it flows in every direction equally. It acts like a flow of particles thousands of times more tiny than electrons, and so, it flows through matter. No matter can shield completely from the flow of this energy field. But, a tiny percentage of the flow does happen to collide with the electrons, atoms and molecules of matter as the energy flow moves through matter. The bigger the chunk of matter, the more of the energy flow collides with it. The collisions convert the energy into additional mass, which is why our Sun is not losing mass as rapidly as theory would predict. The situation is like this:

The force of the Zero-Point Energy field is slightly reduced having passed through (and interacted with) the large mass of the Earth. This reduced strength is indicated in the diagram by the light-blue arrows. The incoming Zero-Point Energy field is not reduced in strength in any significant way as the molecules in the atmosphere are not nearly as tightly packed as those in the matter which makes up the Earth itself. The imbalance of these two thrusts causes a net push towards the surface of the Earth.

For clarity, the diagram only shows the field acting in one direction, while in reality, the same situation applies in every possible direction around the planet. When you let an object go and it moves towards the surface of the planet, it is not being pulled down by “the force of gravity”, but instead, the downward push of the Zero-Point Energy field is greater than the upward push of the Zero-Point Energy field which has just passed through the planet. The object moves “downwards” because the push from above is greater than the push from below.

Exactly the same thing applies to cause the effect that a mountain appears to have on a pendulum. In reality, the mountain has no effect on the pendulum, apart perhaps from a minor electrostatic influence. The main effect is caused by the flow of the Zero-Point Energy field:

Here, the (very roughly drawn) mountain, reduces the push of the Zero-Point Energy field which passes through it, due to its interaction with the matter with which it collides on its trip through the mountain. The push of the Zero-Point Energy field on the side of the pendulum is not diminished, so there is a net push towards the mountain and that makes the pendulum move in the direction of the mountain. The effect is not very large, so the pendulum does not move much out of the vertical as the downward push towards the surface of the planet is quite marked, so the pendulum needs to be very near the mountain for this effect to be observed.

This can also be seen in the Casimir Effect where two non-magnetic metal plates, which are not carrying an electrostatic charge, are suspended very close to each other. The plates do not hang straight down but move towards each other. This is the same effect as is caused by a mountain near a stationary pendulum, or plumb-line. Each plate screens out a little of the Zero-Point Energy field which passes directly through both plates, so the second plate gets slightly less of a push:

The result is that between the plates, the horizontal force pushing them is unbalanced. Hang just one plate up and the horizontal Zero-Point Energy ("ZPE") forces coming from the right exactly balance the ZPE forces coming from the left, and the plate hangs vertically below its point of suspension with the supporting cord (shown in red in the diagram above) hangs vertically. But with two plates as shown, the push from the left is reduced very slightly as it passes through the left hand metal plate. This means that there is a lesser push from left to right on the right hand plate. This causes the plate to move very slightly to the left, until the horizontal pull caused by the red cord not being vertical, just balances the difference in the ZPE thrusts on that plate. So, the right hand plate moves slightly to the left.

The same thing happens with the left hand plate. The ZPE thrust coming from the right is slightly reduced as it passes through the right hand plate, and the left hand plate moves slightly to the right until the angled pull of its supporting cord balances the net thrust on that plate. The overall effect is that the gap at point "A" in the diagram is very slightly larger than the gap at point "B", though the amount is not nearly as great as suggested by the diagram, which has been deliberately exaggerated to show the effect clearly. There is nothing complicated about this, it is just simple common sense. Remember that the pull of the supporting cord "C" is the exact equivalent of a vertical force "D" along with a horizontal force "E". Here, the vertical force D exactly matches the weight of the plate, and the horizontal force E exactly matches the unbalanced ZPE force (if they did not match exactly, then the plate would move until they did). The further away from the vertical that the plate moves, the greater the resulting horizontal force caused by the pull of the supporting cord.

Tesla expressed this in a very slightly different way in his **Dynamic Theory of Gravity** (1897) which states that all bodies emit microwaves whose voltage and frequency are determined by their electrical contents and relative motion. He measured the microwave radiation of the earth as being only a few centimetres in wavelength. He said that the frequency and voltage were influenced by the velocity and mass of the earth, and that its "gravitational" interaction with other bodies, such as the sun, was determined by the interaction of the microwaves between the two bodies.

If you find the concept of producing a driving force through pushing against the space-time continuum to be difficult to accept, then perhaps you should consider the US Patent granted to Boris Volfson on 1st November 2005. The important thing about this patent (which is crammed full of long words) is not whether or not it presents a realistic mechanism for a practical space drive, but the fact that the US Patent Office in the year 2005, granted the patent after what presumably was careful consideration. With that in view, it is hardly possible to consider Tesla to have been totally confused when he designed (and built) his "electric flying machine" which operated by pulling on the space-time field.

Tesla used high voltage at gigahertz frequencies for his electropulsion system. The propulsion of a vehicle powered by a Tesla drive is by the use of an additional AC generator at the back (which stiffens the space-time continuum behind the vehicle) and a DC 'brush' generator at the front (which weakens the space-time continuum in front, causing the vehicle to be pulled forwards).

Tesla was very astute. He deduced that 'empty space' actually contained:

1. Independent carriers which permeate all space and all matter and from which all matter is made. These carry momentum, magnetism, electricity or electromagnetic force, and can be manipulated artificially or by nature.
2. 'Primary Solar Rays' (starlight) which travel at the speed of light, having frequencies far above X-rays, gamma and UV radiation.
3. 'Cosmic Rays', particles in space propelled by the Primary Solar Rays.
4. X-rays, Gamma rays and UV electromagnetic waves, all of which travel at the speed of light.
5. Ordinary visible and Infra-Red electromagnetic waves which travel at the speed of light.
6. Rapidly varying electrostatic force of enormous potential, emanating from the earth and other gravitational bodies in space.

When we grasp the actual nature of the universe, it becomes clear that we have a much larger range of opportunities for producing usable energy in large quantities and at minimal cost.

Additional information can be found in Boris Volfson's US Patent 6,960,975 of November 2005 "Space Vehicle Propelled by the Pressure of Inflationary Vacuum State" which is reproduced in the Appendix.

If you find the thought of generating a gravitational field, difficult to come to terms with, then consider the work of Henry Wallace who was an engineer at General Electric about 25 years ago, and who developed some incredible inventions relating to the underlying physics of the gravitational field. Few people have heard of him or his work. Wallace discovered that a force field, similar or related to the gravitational field, results from the interaction of relatively moving masses. He built machines which demonstrated that this field could be generated by spinning masses of elemental material having an odd number of nucleons -- i.e. a nucleus having a multiple half-integral value of \hbar , the quantum of angular momentum. Wallace used bismuth or copper material for his rotating bodies and "kinnemassic" field concentrators.

Aside from the immense benefits to humanity which could result from a better understanding of the physical nature of gravity, and other fundamental forces, Wallace's inventions could have enormous practical value in countering gravity or converting gravitational force fields into energy for doing useful work. So, why has no one heard of him? One might think that the discoverer of important knowledge such as this would be heralded as a great scientist and nominated for dynamite prizes. Could it be that his invention does not work? Anyone can get the patents. Study them -- Wallace -- General Electric -- detailed descriptions of operations -- measurements of effects -- drawings and models -- it is authentic. If you are handy with tools, then you can even build it yourself. It does work.

Henry was granted two patents in this field: US Patent 3,626,605 -- "Method and Apparatus for Generating a Secondary Gravitational Force Field", Dec 14, 1971 and US Patent 3,626,606 -- "Method and Apparatus for Generating a Dynamic Force Field", Dec 14, 1971. He was also granted US Patent 3,823,570 -- "Heat Pump" (based on technology similar to the above two inventions), July 16, 1973.

Dr Peter Lindemann gave a lecture at the TeslaTech conference which is very informative and which I would highly recommend. It is available on DVD from <http://www.free-energy.ws/products.html> under the title of "Tesla's Radiant Energy". He makes a number of important points, some of which are repeated here.

We tend to think of the battle for industrial electricity to have been between Thomas Edison's DC system and Tesla's AC system, with Tesla winning. Unfortunately, while true, that is not the full story as Tesla moved on from AC to more powerful systems, and Tesla lost out on those systems, leaving us today, with a workable, but much inferior system. We need to see the overall picture clearly. James Clerk Maxwell produced his famous equations, relating electricity and magnetism (which are actually two faces of a single entity called "electromagnetism"). Subsequently, H.A. Lorentz damaged those equations, throwing away the parts which showed that free-energy was available for use if we knew how to access it.

Our present day position has grown up where, while we realise that "gravity" is 10^{39} times less powerful than electromagnetism, we see "static electricity" as a weak and useless thing which needs to be avoided. The reality is quite different as Tesla points out and demonstrates. Tesla describes "static" and "radiant" energy as being a force which appears to have no ultimate limits at all. That is, it is capable of providing unlimited power. Our knowledge of this power is so inadequate that we believe that power can only flow in a circuit which is a closed-loop and the power flow has to be a stream of electrons. This is most definitely not the case.

The more powerful radiant energy flows like an electrically charged sound wave passing through incompressible air and which can be fed down a single wire without the slightest difficulty. In fact, you can even skip that one wire and use the earth instead, transmitting power with what appears to be no wires at all. The actual, final and most important contest was between closed-loop electricity and single-wire power transmission, and that contest was one which Tesla lost.

The nature of this radiant energy is so different to what we think of as conventional electricity that it is perfectly possible to light a filament light bulb held in one hand, while grasping a single wire in the other hand. When doing this, there is no sensation whatsoever and nothing at all is felt. This has been demonstrated and a video (<http://video.google.com/videoplay?docid=-6461713170757457294>) of that demonstration is on the web at this time.

In his lecture, Dr Lindemann remarks that his understanding of the subject has been helped considerably by the book (<http://www.free-energy-info.tuks.nl/TeslaBook.pdf>) "The Inventions, Researches and Writings of Nikola Tesla" and the book (<http://www.datafilehost.com/download-c74378fc.html>) "The Secrets of Cold War Technology - HAARP and Beyond" which describes some of the early work done by Tesla. He also praises the book "Tesla's Vocabulary for Dummies" which is a joke on his part as there is no such book in spite of his appearing to show some quotations from it in his DVD lecture.

One feature of radiant energy which becomes clear from Tesla's description of it, is that the most useful effects which can be gained from it, start at a DC pulse frequency of 1 MHz which is far higher than experimenters use today. He stresses that we do not actually know the exact nature of electricity and that all of our present day measuring instruments are based on electron theory and so just do not measure radiant energy. In a way, it is a bit like the difference between AM radio and FM radio. Both are perfectly valid and work well, but an AM radio will not receive an FM radio signal and an FM radio will not receive an AM radio signal. Unfortunately, radiant energy is much more powerful than conventional electricity and it is not dangerous like electricity is. It should be noted that Hermann Plauston's very detailed patent - US 1,540,998 (<http://www.free-energy-info.tuks.nl/PatD8.pdf>) is on methods of capturing and using this radiant energy, and he describes any multi-aerial systems which produce a net output of 100 kilowatts as being a "small" system. I don't know about you, but I would settle for a system which produced less than 10% of that fuel-less output.

The best information on radiant energy comes from the writing of Tesla and Dr Lindemann draws attention to one of Tesla's patents, US 685,957 (<http://www.free-energy-info.tuks.nl/PatD37.pdf>) which explain how this radiant energy can be captured and used. Tesla also used a motor design which is effective with this type of energy. The motor has two windings, the first being fed directly and the second one receiving a 90 degree delayed pulse through a capacitor.

One thing that Tesla points out is that there is an incompressible gaseous medium filling the universe and which is composed of particles which are much smaller than hydrogen atoms. Mendeleev who constructed the table of elements indicates quite clearly that there should be two gaseous elements which are lighter than hydrogen, but he did not put them in his table because he did not know what they are.

The Nature of Gravity by Maurice Cotterell.

The comments by Joseph H. Cater later in this chapter include the statement that gravity is electromagnetic radiation of a frequency just below that of infra red. The extract from Karl Schappeller's work, also later in this chapter, states exactly the same thing and the same frequency. The extracts from Joseph Newman's

book, also later in this chapter, point out the effect of electron spin on attraction and repulsion. The document <http://www.free-energy-info.tuks.nl/Cotterell.pdf> is a paper on gravity by the very able Maurice Cotterell, part of which is quoted here:

How Gravity Works

“How Gravity Works” explains how Electricity and Magnetism work together to produce the force of Gravity and in doing so, they reveal the underlying science behind Newton’s equation which he tried in vain to uncover, namely, the reason why Gravity is proportional to the masses of two attracting objects, why it grows weaker in proportion to the square of the distance between them, and the nature of the “Gravitational Constant” which continues to perplex researchers to this day. It explains why all objects accelerate to Earth at 32 feet per second every second. It explains why the atom is comprised of eight orbital shells and why those shells fill with electrons in the way that they do. It explains how permanent magnetism works at atomic level, the nature of so-called ‘Dark Matter’, the reason why spiral galaxies are spiral, why the centre of the Earth is boiling hot and how the Earth’s magnetic field is generated.

Scientists cannot understand why the positive protons on the centre of atoms simply do not spring apart – their positive charges repelling each other. In 1935, a researcher named Yukawa suggested that another substance or particle must exist to ‘glue’ the protons in the nucleus together - a kind of atomic ‘velcro’. But an objector to Yukawa pointed out that if indeed that were the case, then there would have to be two kinds of velcro - a velvet side and a hook side (so to speak). But another researcher pointed out that protons covered in the velvet-side would not stick to other protons covered in the velvet-side, and that protons covered in the hook-side would not stick to other protons covered with the hook-side. So, another researcher pointed out that for such a scheme to work, there would have to be three types of each of the three types. Thus, the crazy field of Particle Physics was born. In the decades that followed, Particle Physicists were granted billions of dollars to find out what makes the atom stable. Since then, they have been searching for more than 300 imaginary sub-atomic particles. The Concise (Oxford) Science Dictionary comments:

“... the whole elaborate theory is circumstantial... none of the smaller particles have ever been identified in experiments... the theory does not claim to have been verified”.

Electricity Gravity Magnetism

Cotterell shows that none of the particles actually exist, and more importantly, that none are necessary. To explain why the atom does not spring apart, he returns to firm ground and to the 1930s pioneering work of Ernest Rutherford and James Chadwick and shows that by simply changing the perceived shape of the electron and neutron, the gravitational mechanism is exposed, explaining away the mysteries of the atom and many of the mysteries of the cosmos.

Summary Part 1:

(A) A coil-shaped electron (shown in black) makes the hydrogen atom dynamic [come alive]. The amount of **helically polarised electric field** forced from the poles of the proton is maximum when the electron is horizontal, that is, after 180 or 360 degrees of orbital travel. Shown at the top left is the plan view of a hydrogen atom. The horizontal electron slices through the electric field (shaded pink). A magnetic field is induced into the coil which pushes against the electric field, causing it to topple on it's own axis (like the opposing blades of a windmill) as it orbits the positive proton.

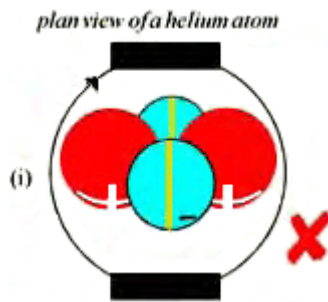

The orbiting coil-like electron sucks energy from the proton causing the proton to compress, release heat and cool rapidly.

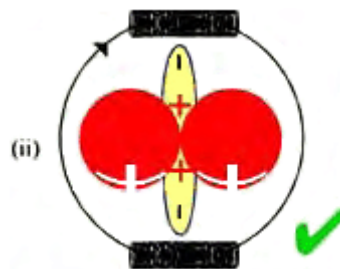

Once the spinning electron-magnet passes the vertical position, the super cold proton sucks in ambient heat and expands rapidly; compression and expansion of the proton results in cyclical changes of capacitance [electric field] proportional to the surface area between the particles.

(iii and vii) The **ends** of the electron-magnet radiate maximum amounts of **helically polarised magnetic energy** after 90 degrees and 270 degrees of orbital travel [when vertical]. Hence the magnetic and magnetic radiation is displaced by 90 degrees and the electromagnetic (EM) radiation from the northern sector is displaced in phase by 180 degrees from that of the southern sector.

(B) (i) The orthodox view of a helium atom (containing two neutrons) precludes an understanding of gravity - each electron is passive [dead] and the spherically shaped neutrons render the atom unstable. Moreover, the electron is shown as a purely 'electric' particle when in fact it is electric for only half the time, and magnetic for half of the time. **The electron is an 'electromagnetic' particle.**

(ii) This new view of the helium atom accommodates a gravitational mechanism - the coil-shaped electrons bring the atom to life and the spike-shaped neutrons make the atom (the contents of the old neutron and the spiked neutron being identical). Supporting evidence: 31/3/08 researchers of the Hohn-Meitner Institute in Berlin announced that "neutrons behave like compass needles" – Science Daily.

(C) hydrogen spins axially and autonomously and so it radiates helically polarised ElectroMagnetic energy into space. [Supporting evidence: 'hydrogen radiates helically polarised EM energy' www.sciencenews.org].

Helium [the only electrically geometrically symmetrical atom to contain spiked neutrons] also spins axially and autonomously and hence, likewise radiates helically polarised electromagnetic energy. In free space, hydrogen and helium are prime movers in the gravitational mechanism. Other atoms cannot **autonomously** radiate helically polarised electromagnetic energy because they do not spin axially or autonomously. However, when helically polarised electromagnetic radiation from hydrogen or helium bombards neighbouring atoms, it causes the nucleus of those atoms to spin in the same direction and, at the same time, causes the orbiting electrons in a cascade of atoms to synchronize their spin. As a result, the magnetic moments of orbiting electron-magnets in a cascade of atoms attract each other. This is the force of Gravity.

Summary Part 2:

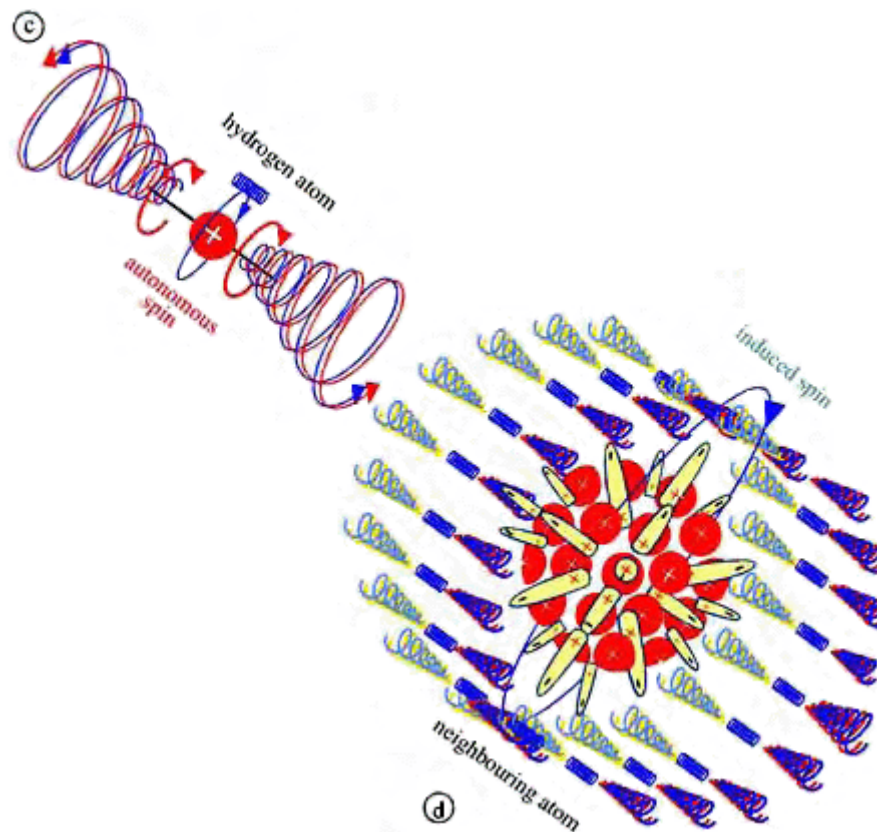

(2A and 2B) The 'Motor Effect'; helically polarised electromagnetic radiation from the hydrogen atom acts upon the negative charges of the neighbouring atom, causing the nucleus and the electron cage to spin axially and at the same time, synchronizes the spin of the electrons in both atoms [Supporting evidence: [Nature 2009;458 \(7238\):610 DOI:10.1038.nature07871 \(persistent spin helix\)](#)]. The mass of the electron is twice that of the neutron-negative charge, hence the torque on the electron-cage is twice that on the neutron-negative charges in the nucleus. Thus, the electron-cage spins faster than the nucleus.

(2B) The 'Generator Effect'; orbiting electrons in the neighbouring atom now 'generate' helically polarised electromagnetic radiation. The power of the atomic 'generator' is proportional to the differential speed between the nucleus and the electron cage and to the number of orbiting electrons (atomic mass).

Electromagnetic output is a function of the number of electrons [atomic mass] ('g') AND of the difference in rotational speed between the nucleus and the electron cage ('f').

(2C) Gravity radiation from the hydrogen atom bombards neighbouring atoms sucking them towards the source of the radiation. [Here, to facilitate explanation, the magnetic wave (shown in blue) is shown radiating from the nucleus whereas in actuality, it radiates from the orbiting electron].

(2D) The corkscrew-style electromagnetic radiation from the neighbouring atom now, likewise, sucks nearby atoms towards itself. Both atoms suck in the same direction, thus gravity from the Sun and the Moon pull in the same direction. [To facilitate explanation, the electric waves (shown in red) are shown radiating from orbiting electrons].

(2E) As gravity radiation propagates and moves away from the atom, it decreases in field strength [per metre squared]. For every unit of distance travelled, the radiated energy diverges geometrically. This causes the radiated energy to reduce by the square of the distance travelled ("d²"). The numbers inside the square in the diagram above show the field strength of the radiating electromagnetic energy in volts per square metre. [Squares are used here just for illustration purposes as the diverging wave is actually conically-helical as seen in Figure 2F].

(2F) The frequency of the helically polarised electromagnetic radiation from the Earth remains constant. However, as **m** approaches **M**, the spiralling electromagnetic radiation accelerates the differential rotation between each atomic nucleus and electron-cage of which **m** is made. As a result, the 'relative' atomic frequency increases and hence the output of the 'atomic generator' increases, uniformly increasing the attracting electromagnetic Force between **m** and **M** in accordance with a square-law scale as **m** proceeds along the electromagnetic spiral. **M** thus attracts **m** with square-law [**d**²] uniform acceleration. In the diagram on the right, **m** is shown spiralling towards **M** with the electromagnetic wave stationary, but in reality, **m** approaches **M** in a straight line as the wave spirals across **m**.

(2G) Hence Isaac Newton's equation for the force of gravity; where the force is proportional to the masses (**m** and **M**) of the two attracting bodies and the strength of the force decreases inversely with the square of the distance between them (**d**²).

$$F = GmM/d^2$$

G is Newton's gravitational constant **6.67428 x 10⁻¹¹ N m² kg⁻²** - the instantaneous alternating magnetic force between any two electron-magnets in neighbouring atoms.

Maurice Cotterell gives a more advanced and in-depth explanation of this process in his latest book "FutureScience" in which the introduction says:

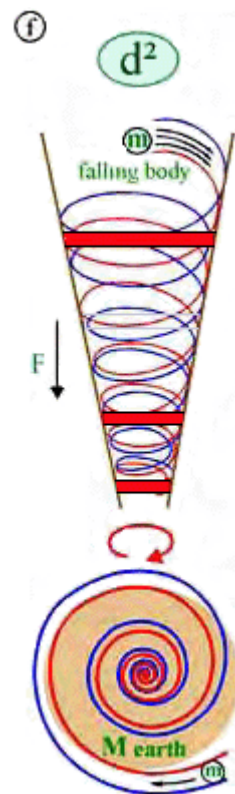

The 12 great mysteries of Physics

You can be forgiven for believing that Isaac Newton discovered the force which makes apples fall to the ground, but he did not. He simply gave the force (**F**) a name ("Gravity") and noted that the strength of the force, whatever it might be, depends on the size of the Earth (Mass **M**₂). He also figured out that the strength of force on the apple depends on how far away the apple is from the Earth to begin with and he noted, like Galileo before him, that as an apple falls it speeds up and travels faster and faster until it hits the ground.

At first, Newton set down the relationship between the force and the masses in a shorthand way (a formula) saying that **F** (the strength of the force) could be found by multiplying **m**₁ by **M**₂ and then by dividing the result by the square of the distance between them (**d**²). There was just one problem: every time he did the calculation he finished up with the wrong answer. He eventually discovered that the only way to get the right answer was to multiply the wrong answer by '667 billionths'. He did not know where this tiny amount of force came from, but just like he had done with Gravity, he gave the mysterious number a name – "the Gravitational Constant" **G**. This made his formula **F = G x m**₁ x **M**₂ / **d**². It is hard to believe that since then, that is, for more than 350 years, still no-one understands what gravity is or what causes it or why we have to multiply the wrong answer by **G** to get the right one. To this day, no-one understands what **G** is or even where it comes from. That's how sophisticated we are. No-one understands why objects fall to the ground.

The second most embarrassing problem for modern Science is that no-one understands why positive charges in the middle of atoms simply do not just spring apart which is what you would expect, given that positive repels positive. To overcome the contradiction, physicists decided that the positive charges must be glued-together in some way and so, for the past 75 years they have been searching for the 'glue' or more precisely, more than 300 types of glue – but as yet have not found any.

Also, no-one understands (given that positive attracts negative), why the orbiting negative electrons of atoms do not simply get sucked into the positive bits in the middle of the atom. They just 'cannot understand it'.

When you place a magnet on the door of a refrigerator, you probably imagine that scientists understand how a magnet actually works, but they do not. As far as they are concerned, it seems to work by *magic* so they gave it the name *magnet*.

Switch on the light and you no doubt take it for granted that the people who supply the electricity understand how it works, but they do not. Physicists are pretty sure that an electrical current is simply the movement of atomic negative charges along a wire. The problem is that no-one understands why, whenever a current flows, a magnetic field appears around the wire.

When they look skywards at night, astro-physicists cannot understand what makes the stars cluster together into galaxies, because their calculations contradict what their eyes can see. To overcome this, they say that there must be other sources of gravity out there, like planets and dust which cannot be seen because it is dark. So they named their fantasy planets 'dark matter', at least for the time being, until they can figure out why their calculations do not make sense. Neither can they understand why stars spiral into galaxies, but they cling to the hope that when (or if) they understand how gravity actually works, that the reason for the double-spiral of galaxy formation will become clear.

"FutureScience" explains in a simple way, how Electricity and Magnetism work at atomic level, and how they work together to produce the force of Gravity and in so doing, reveal the underlying science behind Newton's equation – the underlying science which he tried in vain to uncover – the reason why Gravity is proportional to the masses of the two attracting objects, why it grows weaker in proportion to the square of the distance between them, and the nature of the mysterious 'Gravitational Constant' which continues to perplex researchers to this day. It explains why all objects accelerate to Earth at 32 feet per second every second. It explains why the atom is comprised of 8 orbital shells and why the shells fill with electrons the way that they do. It explains the nature of so-called 'dark matter', the reason why spiral galaxies are spiral, why the centre of the Earth is boiling hot, how the Earth's magnetic field is generated, how to generate gravity waves, how gravity waves can be used to produce unlimited quantities of free energy, how to generate antigravity waves, how antigravity waves can be used to de-couple hydrogen bonds in water, separating hydrogen from oxygen and providing unlimited supplies of free hydrogen to fuel hydrogen-powered cars, and how antigravity radiation can be used to cause the disintegration of matter in water and living tissue (phasor weapons technology).

The book goes on to explain the cause of the Sunspot cycle and how the Sun affects life on Earth: the cause of global warming and global cooling, how the 289-day spinning Sun regulates fertility in females, how the Sun's radiation causes 12 types of genetic mutations which result in 12 types of personality (sun-sign astrology), how sunspots cause schizophrenia, how the Sun controls bio-rhythms and our day-to-day behaviour, how the Sun causes catastrophe cycles and the rise and fall of civilizations, and how mobile phones and power lines cause cancer.

How the discoveries were made

In 1935, in an attempt to explain why protons in the centre of atoms do not simply spring apart, a researcher named Yukawa suggested that another substance or particle must exist to 'glue' the protons in the nucleus together - a kind of atomic 'velcro'. But an objector to Yukawa pointed out that if indeed that were the case, then there would have to be two kinds of velcro - a velvet side and a hook side (so to speak). But another researcher pointed out that protons covered in the velvet-side would not stick to other protons covered in the velvet-side, and that protons covered in the hook-side would not stick to other protons covered with the hook-side. So, another researcher pointed out that for such a scheme to work, there would have to be three types of each of the three types. Thus, the crazy field of Particle Physics was born. In the decades that followed, Particle Physicists were granted billions of dollars to find out what makes the atom stable. Since then, they have been searching for more than 300 imaginary sub-atomic particles. The Concise (Oxford) Science Dictionary comments:

"... the whole elaborate theory is circumstantial... none of the smaller particles have ever been identified in experiments... the theory does not claim to have been verified".

FutureScience shows that none of the particles actually exist and, more importantly, that none are necessary. To explain why the atom does not spring apart, the Author returns to firm ground and to the 1930s pioneering work of Ernest Rutherford and James Chadwick and shows that by simply changing the perceived shape of the electron and the neutron, the gravitational mechanism is exposed, explaining away the mysteries of the atom and many of the mysteries of the cosmos. The book is aimed at the general reader with no prior knowledge of Science and it uses many illustrations to convey the concepts simply and concisely.

Maurice Cotterell's web site is <http://www.mauricecotterell.com/>

Maurice also comments on the recent Cold fusion generator development of Rossi as follows:

E-Cat generator **not** 'cold fusion'

The Energy Catalyzer (also called E-Cat) is a purported **cold fusion** or Low-Energy Nuclear Reaction (LENR) heat source built by inventor Andrea Rossi with support from physicist Sergio Focardi. An Italian Patent, which received a formal but not a technical examination, describes the apparatus as a 'process and equipment to obtain exothermal reactions, in particular from nickel and hydrogen'. Rossi and Focardi say the device works by infusing heated hydrogen into nickel, transmuting it into copper and producing heat. An international Patent Application has received an unfavorable International preliminary report on patentability because it seemed to '**offend against the generally accepted laws of physics and established theories**' and to overcome this problem the Application should have contained either experimental evidence or a firm theoretical basis in current scientific theory. (<http://www.peswiki.com>)

**FREE
ENERGY?
YES
but it's not
'Cold Fusion'**

How they think it Works: The Energy Catalyzer works—they believe—by placing nano to micro sized particles of nickel powder in a reactor along with pressurized hydrogen gas and special undisclosed (for proprietary reasons) catalysts. When the contents of the reactor is heated (using a series of resistors in the reactor) to approximately 400 to 500° C., *nuclear reactions* start taking place. The strength of the reaction can be changed by varying the pressure of the hydrogen in the reactor. The output energy can be up to 400 times the input energy. No precious metals or radioactive substances are placed in the reactor. After the reactor is turned-off the reactor can be opened and no radiation can be detected. The process appears to transmute nickel into copper and trace amounts of other elements such as zinc. *It will not work with deuterium (heavy hydrogen)—but they don't know why.*

if it's not 'Cold Fusion', how does it really work?'

...it works by '**Periodic Scaling**' →

How to generate gravity waves, and free energy, using 'Periodic Scaling'

ambient heat and light

Fill each of 120 containers with one each of the elements and align the containers in a straight line in rising atomic number order. How does it work? Gravity waves from the hydrogen atoms in the hydrogen container will bombard the container next in line containing helium. The helically polarized electromagnetic gravity waves from the hydrogen container will act upon the spiked-neutrons in the helium atoms causing the helium atoms to spin axially in the same direction. The helium atoms will now generate and radiate helically polarized gravity waves, sucking-in ambient heat to fuel the process. In this way ambient heat is converted to gravity waves and more heat. Helically polarized gravity waves from the helium atoms will act upon the spiked-neutrons in the lithium atoms causing those atoms to spin axially in the same direction. The lithium atoms will now generate and radiate helically polarized gravity waves, again, sucking-in ambient heat to fuel the process. This sets up a chain reaction along the line of containers; hydrogen, the prime-mover, activates every atom in the chain. Containers along the chain will become increasingly hotter and massive amounts of gravitational energy and heat will radiate from the end of the chain following atom 119, ununennium. [from *FUTURESCIENCE*—forbidden science of the 21st-century by Maurice Cottrell]

Note: the line of containers will be influenced by gravity waves from the Earth and so should be stacked vertically, silo-like, with hydrogen uppermost. Water may be used in place of hydrogen, and dangerous elements may be omitted, at a cost to efficiency.

The E-Cat generator uses 'Periodic Scaling' to generate heat in the same way; the hydrogen fuel, used in the process, sucks-in ambient heat and converts the heat to gravity waves—that's why liquid hydrogen is the most effective super-coolant. The corkscrew-style electromagnetic gravity waves from the hydrogen atoms then excite the nickel atoms causing the nickel to get hotter. The hydrogen fuel then sucks-in more heat *from the nickel* and radiates more gravity waves that again bombard the nickel. Some of the fuel is consumed in the process. This cumulative excitation continues until the availability of heat in the ambient air, and nickel, is constrained by energy transfer considerations.

Figure 7 (in *How Gravity Works* [see www.MauriceCotterell.com]) showed how the first two atomic orbital shells are offset by 90°. In this case, the neutron-negative occupies the first *virtual* orbital 'radius'. The electromagnet orbit must therefore be offset by 90°, as shown. Because of this, the electric wave from the neutron-positive clashes with the magnetic wave from the orbiting electromagnet, and vice-versa, and the two electromagnetic waves cancel. Hence, deuterium cannot radiate gravity waves.

here's the 'smoking-gun'; the E-Cat generator will not work with deuterium [heavy hydrogen]—because deuterium cannot radiate gravity waves

proof, if proof were needed, that the process must work by 'Periodic Scaling'

John Searle's Permanent Magnet Drive/Generator.

Professor John R.R. Searle of Britain developed an electrical generation system based on two rings of magnets being spun relative to one another. The magnet orientations oppose each other to produce a magnetic splatter field.

The outer magnets in the diagram above are referred to as “rollers”. When three rings of rollers are placed one inside the other, then the outer ring rotates of its own accord, without any external power being applied. If pick-up coils are placed around the outside, then electrical current is generated with a COP of infinity. The method of imprinting the necessary magnetic pattern on both the rollers and the stators is a difficult and expensive process.

Dr. Terry Moore has recently built a replication model of this Searle technology and his model video is available at <http://www.youtube.com/watch?v=bb3N1epMG7A>. The Searle device also demonstrates a gravitic effect and John has built what would loosely be described as a “flying disc” using this technology. If high voltage is applied to the device when it is rotating, then a surrounding corona develops and strong upward electrogravitic forces are generated.

Dave Lawton's Gravity-Wave Detector.

It has been reported that Nikola Tesla made a device which allowed him to hear sounds at great distances. I have never seen any details of the circuitry used by Tesla. However, Dave Lawton has produced such a device, and he reports that he could hear conversations taking place four and a half miles away from him. Interestingly, the sounds from that distance were also travelling through a solid stone wall some three feet thick. The circuit for this device is described in this document.

In my opinion, the device is not picking up audio signals in the manner of a conventional microphone where air pressure waves vibrate a transducer, creating an electrical signal which is then amplified. The interesting thing is that it is distinctly possible that some other mechanism is coming into play here. This opinion is supported by the fact that Dave's circuit is an upgraded version of a monopole gravity-wave detector. Dave used this device to record the “sound” of the Shumaker-Levy comet colliding with Jupiter.

The circuit shown here is quite conventional electronically speaking, comprising of two 741 operational amplifiers connected as a two-stage amplifier. The unusual feature is where a small amount of white noise is being fed into the microphone input:

The white noise is generated by the 5-volt zener diode. The level of this white noise component is controlled by the 1.5 megohm variable resistor plus the 10K fixed limiting resistor. While the range of these two components is 10K to 1.501 Meg. the working setting is normally very high and so only a very small amount of white noise is fed into the input of the first 741 op. amp. to modify the microphone input.

The adjustment of this injection of white noise is the main control of this most unusual circuit, and it has been found that when the setting is just right, the circuit has the feel of a public address system just about to go unstable from positive feedback. The unit build looks like this:

The theory of operation was put forward by Gregory Hodowanec in the April 1986 issue of the Radio-Electronics Magazine, where he puts forward the theory that the source of noise in electronic devices is caused by gravitational waves and he suggests that there are monopole gravity waves. This does not oppose the gravity waves predicted by Einstein. Gregory views these monopole gravity waves as being much stronger than those suggested by Einstein, and consequently, much easier to detect.

He also suggests that monopole gravity waves have been seen for many years and have been described as “low frequency noise” signals or “flicker noise”. These signals have also been called Microwave Background Radiation, supposedly caused by the “Big-Bang” though this cause is disputed by some.

Gregory views our universe as a finite, spherical, closed system, i.e. a black body. Monopole gravity waves propagate in Planck time so their effects appear everywhere almost simultaneously. Gravity wave energy can be imparted to ordinary objects. So it is suggested that the fact that a fully discharged electrolytic capacitor can develop a charge when disconnected from all circuitry, is down to the interaction of the capacitor with monopole gravity waves.

Gregory suggests the following circuit for examining monopole gravity waves:

Details of this and the theory can be found at www.rexresearch.com/hodorhys/remag86/remag86.htm. Dave has taken that circuit and extended it substantially to give added gain plus a controlled feed of white noise, without relying on the characteristics of a capacitor, capacitors being notoriously variable in precise characteristics.

The unit is operated by turning the gain up until the circuit just reaches self-oscillation, and then backing the gain off very slightly. The white noise source is then adjusted until the unit is producing a somewhat echoing quality to the sound. The result is a device which has unusual characteristics. The circuitry is so simple and cheap, that you can easily try it out for yourself.

Butch Lafonte's Motor/Generator.

Butch has designed an intriguing Motor / Generator system based on the balancing of magnetic and electrical forces. This clever design operates according to the following statements made by Butch:

1. If a magnet is moved away from an iron-cored coil, it generates a voltage:

The voltage generated for any given magnet and speed of movement, is directly proportional to the number of turns of wire which make up the coil.

2. If a magnet is moved away from an air-cored coil, it also generates a voltage. However, the big difference is that the voltage is of the opposite polarity. In other words, the plus and minus connections are swapped over:

Again, the voltage generated for any given magnet and speed of movement, is directly proportional to the number of turns of wire which make up the coil.

So, if these two arrangements are joined together, they produce a system where the voltages cancel each other exactly, provided that the number of turns in each coil are adjusted to produce exactly the same voltages. The mechanical attraction and repulsion forces also balance, so the circuit can be arranged to have no net effect when the rotor is rotated:

It follows then, that this motor arrangement could be introduced into an existing circuit without affecting the operation of that circuit. The arrangement would look like this:

Here, there is no net electrical or magnetic drag on the rotor as the magnets move away from the coils. The battery supplies current to the load in the normal way and rotor arrangement has no effect on the operation of the circuit.

However, when the rotor reaches 100° or so, past the coils, the On/Off switch can be opened. This leaves the rotor in an unbalanced condition, with there being an attraction between one magnet and the iron core of one coil. There is no matching repulsion between the other magnet and the air core of the other coil. This produces a rotational force on the rotor shaft, keeping it spinning and providing useful mechanical power which can be used to generate additional power. This extra mechanical power is effectively free, as the original circuit is not affected by the inclusion of the rotor system.

From a practical point of view, to give high rotational speed and long reliable life, the On/Off switch would need to be an FET transistor with electronic timing related to the rotor position.

There is no need for the rotor to have only two magnets. It would be more efficient if it had four:

Or better still, eight:

And if you are going to have eight, there is no need to have the V-shaped cut-outs which just create turbulence when spinning, so make the rotor circular:

And the stator supporting the coils matches the rotor:

Ferrite is a better material for the cores of the coils. The stators go each side of the rotors and the hole in the middle of the stators is to give clearance for the shaft on which the rotors are mounted:

A system of this type needs accurate timing which is solely related to the rate of rotation. This is best arranged by the use of a bistable multivibrator as described in the Electronics Tutorial of Chapter 12. You will notice the two Timing Coils shown at the right hand side of the diagram above. These are used to toggle the bistable On and Off and they are adjustable in position so that both the On and the Off can be set very precisely. The output of the bistable is set to switch an FET transistor On and Off to give circuit switching which is not affected by either the switching rate or the number of times the switch is operated.

The Rotor / Stator combination can be wired to act as either a driving Motor or an electrical Generator. The difference is the addition of one diode:

With this arrangement, for each rotor, all four pairs of Cored coils are wired in parallel across each other, and all four Air-cored coils are wired in parallel across each other. To improve the clarity, the above diagram shows only one of the four pairs, but in reality, there will be four wires coming into the left hand side of each of the screw terminals.

In the case of the Generator arrangement, you have the option to connect each of the four pairs in parallel as in the Motor arrangement or to connect them in series. Connected in parallel, the coils can sustain a greater current draw, while if connected in series, they provide a higher voltage. The voltage could be further increased by increasing the number of turns on each coil.

Joseph Newman's Motor.

Joseph Newman is a man who impresses me. He performs experiments, reports the results and then bases theoretical conclusions on the results of his own experiments. This is the true scientific method.

Joseph has been granted a patent and he has written a book. I would recommend that you buy a copy of his book and help support his work by doing that, but unfortunately, as I understand it, the printing plates for the book were destroyed in a fire and printed copies of his book are effectively unobtainable. You can download a .pdf version from the <http://www.free-energy-info.tuks.nl/> web site but please be aware that the overall file size is 100 Mb and so the download will take quite some time. A background download can be had from <http://www.mediafire.com/view/?oe5obw6offoqfs3> or the alternative <http://www.filefactory.com/file/b4g6b3d/Newman.pdf> link while the link to Joseph's own web site is <http://www.josephnewman.com/>.

In very brief outline, Joseph has built a motor which can access free energy. He has a theory about where the excess energy is coming from and how it is acquired by his designs. He has also built a large stationary motor to demonstrate his theory and he has built a motor into a car. The car engine runs on very minor battery power. Joseph's patent is included in the Appendix.

With the kind permission of the Joseph Newman organisation, I am going to attempt to introduce you to the important scientific conclusions reached by Joseph and the Energy Machine which he designed and which is based on those conclusions. Joseph has a keen enquiring mind and thinks things through for himself rather than blindly accepting everything he is told. This description contains illustrations and wording taken from parts of Joseph's book published in 1984, and I should like to express my thanks for being given permission to use this material.

Joseph Newman's motors all consist of a very powerful permanent magnet which rotates or oscillates in or near a coil with a very large number of turns of copper wire. The coil is energised by a battery pack, and the magnetic field produced by the coil provides the force needed to move the permanent magnet. A mechanical switching device or "commutator" reverses the direction of current flow through the coil every half cycle, and in some models, it also cuts off the current input between the current reversals.

The main difference between Joseph's designs and previous motors is one of scale as Joseph uses very large coils and very large ceramic magnets weighing up to 700 pounds. His smaller motors use powerful rare earth magnets and the coils are wound with 100,000 turns of copper wire. This creates a very high coil resistance and the battery pack voltages are correspondingly high, being in the hundreds to thousands of volts range.

The torque or turning power applied to the magnet in these motors is proportional to the magnet strength, the number of turns in the coil and the current flowing in the coil. In Joseph's motors, very large torques can be developed by very small currents. In one demonstration, a motor running on 3,000 volts at 0.8 milliamps has such power that it is not possible to stop the motor by holding its two-inch (50 mm) diameter shaft, though the current can be raised by trying to stop it, to 3 milliamps, or nine watts of power.

Joseph's motors are different in other ways. If fluorescent tubes are connected across the motor coil, they light up due to the coil's collapsing magnetic field each time the current direction is switched. These fluorescent tubes are used to protect the mechanical switch from arcing damage. The additional power produced in these tubes is at a very high frequency of 10 to 20 MHz. This radio-frequency current has been accurately measured and it exceeds the battery input current by a factor of five to ten times in the different motors. The measured current and voltage were in phase, indicating a real power output.

To understand the thinking behind these motors, we need to follow Joseph's experiments and the deductions which he made from those experimental results. Joseph considered, and thought carefully about statements made by the two scientific giants James Clerk Maxwell and Michael Faraday, and this led him to valuable

insights:

It appears that Maxwell and Faraday were the only people who considered that “lines” of magnetic force are actual physical entities and not just a method of representing notional forces and those “lines of force” are actually streams of **matter in motion**.

Maxwell says: “**In speaking of the Energy of the field, however, I wish to be understood literally.** All energy is the same as mechanical energy, whether it exists in the form of motion or in that of elasticity, or in any other form. **The energy in electromagnetic phenomena is mechanical energy**”.

Joseph then considered Michael Faraday’s Electrical Generator and the implications of the way in which it operated:

Here, a loop of wire is moved downwards from level “A” to level “B”. This movement causes an electrical current to flow leftwards along the wire as shown by the red arrows. Joseph’s question was “why does it go in that direction every time the wire is moved in that way?”

If the wire is moved upwards through the same magnetic field, then the current flowing in the wire moves in the opposite direction. Why? How does the current “know” which way to go?

If you turn the magnetic field round by reversing the position of the magnetic fields and then move the wire loop in the same way as before, the current flows in the opposite direction. How does the current “know” which way to flow, or which way round the magnets are turned as it does not touch them?

The next interesting point is that if the wire loop is moved up and down between the magnets, but turned to be parallel to the flux flowing between the poles, then no current flows in the wire, no matter how quickly the wire is moved up and down.

Another point is that if the wire loop is moved **slowly** up through the magnetic flux, the electric current which flows as a result of that slow movement, **moves at the speed of light**, flowing from "A" towards "B".

Now, if the wire loop is disconnected and turned over, the part which was at "A" now moved to "B", and the same movement of the wire carried out - the current flow is in exactly the same direction although its path along the wire is reversed (because the wire has been reversed). This shows that the direction of current flow is not affected by the wire itself.

According to conventional teachings, this electric current flow was not a result of the magnetic field as the magnetic lines of force were supposed to be imaginary, consisting of Potential Energy and **no** Kinetic Energy. It became clear to Joseph that this conventional teaching was wrong. Instead, it seemed clear that the magnetic field consists of particles which have mechanical characteristics, and those particles must be moving at the speed of light within the magnetic field.

A key question seemed to be: "how does the current 'know' which direction to flow?" as the direction was always consistent. After careful consideration, it occurred to Joseph that the answer was provided by the

actions of a gyroscope:

Here, if the axle of the spinning flywheel, or gyroscope, is pressed downwards it moves off in the direction shown by the red arrows. However, if the axle is pressed upwards:

then the axle moves in the opposite direction as shown by the red arrows. This effect is, of course, reversed if the direction of rotation of the gyroscope is reversed (as it will be if viewed from the other side, in the same way as the current flow direction in the wire is reversed if the magnetic poles are swapped over).

Now, if the gyroscope axle is moved up and down equally on both sides, there is no resulting sideways force:

The action of the gyroscope axle matched the current flow in the wire in every respect, so it became clear to Joseph that the particles flowing between the poles of the magnet were spinning as well as moving at the speed of light. This gyroscopic mechanical motion of the particles accounts for all of the characteristics of the current flow in a wire which is being moved through a magnetic field. This is a major insight on the part of Joseph.

May I remark that these particles are not coming from the magnet itself, but are flowing in from the zero-point energy field, that flow being caused by the broken symmetry of the zero-point energy field generated by the dipole effect of the poles of the magnet. That is why energy can (appear to) be drawn from magnets for years on end.

Joseph then went on to consider the physical aspects of permanent magnets. There were two very significant facts which had to be considered. The first of these is that different materials have markedly different magnetic characteristics:

A bar of soft iron does become a permanent magnet when pulsed briefly with a strong magnetic field, but if exactly the same level of magnetic pulsing is applied to a similar bar of an alloy of iron, nickel and cobalt, a permanent magnet is also produced, but the magnetic field of the alloy is very much stronger than that of the soft iron bar. This shows that the molecular structure of the bar has a major effect on the resulting magnet.

In passing, please be aware that the more powerful magnets available nowadays are so strong that they can easily injure you. If you pick up a magnet and inadvertently get close to a second one, the loose magnet will jump some inches and try to connect to the one in your hand, crushing your fingers in the process and proving very hard indeed to shift in order to deal with the injury. I have also seen it alleged that US 'AlNiCo' (Aluminium / Nickel / Cobalt alloy) magnets are deliberately doped with K40 isotope which renders them useless fairly quickly. The source of this information is highly dubious, but the extra sales advantages to the magnet manufacturers would be significant. Also, the advantages for the people wanting to suppress the creation of free-energy magnet motors would be major as many talented US inventors are likely to think that their successful magnet motors were failures because the magnets appeared to be "drained of power" by being used in their design, when in fact, the design is perfectly good. So I will leave you to make up your own mind about the matter and remark that Bill Muller found that his powerful Chinese-manufactured magnets were in perfect condition after eleven years of use.

Another point which Joseph considered was the fact that when successive magnetic pulses are applied to a ferromagnetic metal bar, the resulting magnetic field strength reaches a definite maximum value, and further pulsing has no further beneficial effect:

This is considered to be the magnetic pulse aligning atoms in the metal. Eventually, all of the atoms are aligned and so not further effect can be produced by further pulsing. This alignment can be destroyed if the metal bar is heated to a sufficiently high temperature, forcing the atoms into such an energetic state that the alignment is lost.

It should perhaps, be stressed here, that the magnet itself does not have any power, in spite of seeming to have. Tom Bearden explains this clearly by pointing out that what happens is that the opposite poles of the magnet created a “dipole” which unbalances the random ‘quantum foam’ nature of the local environment (the zero-point energy field) and that causes continuous energy flows from the environment. The “magnet” power is coming from the environment and not from the magnet itself.

If you find this hard to believe and think that you are just getting back the electromagnetic energy which you pumped into the metal when creating the magnet in the first place, then apply simple arithmetic. Assume that you get back exactly 100% of the original power and calculate how long that amount of power would allow the magnet support its own weight against gravity, when attached to a vertical metal surface. Then ask yourself how come the magnet can do it for years and years on end. Point proved conclusively?

Joseph concluded that the attraction of “unlike” magnetic poles and the repulsion of “like” poles is caused by the gyroscopic spin direction of the actual physical streams of the “lines of force”, which he has shown that both of the scientific giants, Maxwell and Faraday were convinced were actual physical entities. The intuitive genius Nikola Tesla described the zero-point energy field as having the physical characteristics of a gas, capable of having motion, exerting pressure, and yet having particle size so small that it can flow through any physical material. Joseph has concluded that this field flow has a specific spin direction as it flows, certainly for flows caused by the magnetic dipole of a magnet. It should be remembered that the scientific teaching of present day educational institutions is at least fifty years out of date. We have the most unusual situation where the scientific literature of a hundred years ago is actually of better quality than that of today which does not describe the actual world at all well. Currently, misconception is alive and very well.

For example, Maxwell produced equations describing how the world works. Admittedly, these equations are very difficult for people to understand. H. A. Lorentz simplified these equations and his results are mistakenly described as Maxwell’s which they most certainly are not. Tom Beardon illustrates it this way; consider a sailing boat being driven along by the force of the wind against the sails:

Maxwell says that there is a vast swathe of wind blowing across the ocean, capable of powering a long row of a thousand sailing boats side by side. This is the actual physical case. Lorentz has 'simplified' things by saying "we will consider one boat and only one boat. As the rest of the wind does not touch any part of the boat we can ignore it". While that is true for that one boat, what science teaching now says is that the wind can **only** power a single boat. This is not the actual case, as the environmental wind is **not** limited to powering just one boat (sailing regattas would not be much fun if that were the case!). This, of course, is just an illustration. Maxwell's equations cover energy and power for the whole universe, and deal with all cases. Lorentz has taken a sub-set of the conditions described by Maxwell's equations, just the group which apply to "closed systems" – just one boat on the ocean. Science has latched on to this and now confidently states that everything is a "closed" system, when in fact, as the zero-point energy field flows through everything, everywhere at all times, and is capable of supplying unlimited additional energy anywhere at any time, there is probably not a single instance of a "closed" system anywhere in the universe.

Joseph Newman, and all other serious inventors, have to fight against this "conventional" science teaching, which is now so entrenched that it has become the equivalent of religious dogma, and 'scientists' are unwilling to consider valid observations which do not fit in with the very limited Lorentz concept of the environment. They say "perpetual motion is impossible" which means that Newton was wrong when he said that a moving body will keep on moving indefinitely unless some force acts on it to stop it. Presumably, then, the Earth can't keep on orbiting the Sun (gosh, I hope it doesn't stop today as that would be very awkward). Come on – get real !!

You can see then, that when Joseph performs tests and then bases his conclusions on the results of those tests, that he is applying the true scientific method, and people who say that his verified results are impossible because Lorentz says so, are not being scientifically honest. No honest person can ignore genuine scientific observations.

Joseph's deduction that magnetic lines of force are formed of actual physical particles spinning in gyroscopic motion as they move along their magnetic path at the speed of light, was not something which was obvious to scientists, in spite of the fact that both Maxwell and Faraday had both explicitly described these lines of force as being 'kinetic magnetic energy':

As a wire passes in front of and across the end of a bar magnet, the current flows in one direction, pauses, and then flows in the opposite direction. This occurs due to the gyroscopic flow direction of the particles. For instance, on one side of the South end of the magnet, the lines of force spin "up" while on the other side

of that same South end, they spin “down”. A spinning gyroscope will move at right angles to the force acting on it, so as the gyroscopically spinning particles encounter the particles of the wire, they move “up” or “down” the wire at right angles to the direction in which they first encounter the wire. Please note that it is the gyroscopic spin direction of the particles which determines magnetic ‘attraction’ or ‘repulsion’ and not the direction of flow of those particles along their line of force:

It should also be realised that although we draw ‘lines’ of force around a magnetic device, the reality is that these are really shells of force and the magnetic flow is really like water flowing in a river. While we may draw arrows to indicate direction and strength of currents in a diagram of the river, the reality is, of course, that there is water flowing at all points in the river and not just along the lines which we decide to draw. The same applies to the magnetic flow around a magnet, it exists like a solid mass flowing through and around the magnet. You don’t see it or feel it because the particles are so small.

Now to the details of how to construct a device to take advantage of this magnetic movement and output more power than is required to make it operate. Let me remind you again that we are talking here of a Coefficient of Performance (COP) which is greater than 1 in a system which has an overall power efficiency of less than 100%. This is, of course, due to the additional energy flowing in from the zero-point energy field. Joseph visualises the apparent energy gain as being conversion of a small amount of matter into its energy form ($E = mc^2$), and while this is probably correct, it will be particles of the zero-point energy field which are being converted into their energy form and not particles from the metal of the magnet. It must be remembered that the particles of the zero-point energy field keep swapping over from energy to physical form all the time anyway. Energy is never “used up” but merely converted from one form to another and the zero-point energy field contains such a staggering amount of energy that all of the visible matter in the whole of the universe could be created from the energy in a single cc of the zero-point energy field. So, if a few sub-sub-sub-microscopic particles of the zero-point energy field switch into their energy form to produce what looks like excess power to us, that is an item so trivial to the field that it is not even worth mentioning – less than the effect of taking one grain of sand off a beach one hundred miles long. The conventional conception of the way things are is so far away from reality that it is ridiculous, (and that is even without saying anything about the effect that the time axis dimension has on the energy balance and flow of energy).

But back to Joseph’s design. Firstly, he points out that it is generally agreed (courtesy of Gustav Kirchhoff) that in the situation shown here:

In any given instant of time, the amount of current flowing into the system ("X") is exactly matched by the amount of current flowing out of the system ("X"). **But**, if measuring equipment is attached across the coil at the moment of switch-off, an additional amount of current ("X") flows out of the coil. This is generally agreed, and it suggests that a quantity of current "X" flows into the coil and yet a quantity of "2X" flows out of it (COP=2).

Joseph examines this situation in practical detail as follows:

Consider an air-cored coil with an interior diameter of 10 feet, a height of 8.32 feet and would with 1,000 feet of 40-gauge copper wire. That length of wire has a resistance of 1,049 ohms and weighs 0.02993 pounds. If 100 volts DC is connected across it, then a current of about 95 milliamps will flow, which is a power input of 9.5 watts. With just 31.8 turns, it will produce a weak magnetic field of 0,012 Gauss, with a mere 0.000014 Joules of energy stored in it. With a tiny inductance of just 0.003 Henries, if the current is stopped and the ends of the coil shorted together, only an insignificant current would flow.

Now, repeat the experiment, but this time, use 5-gauge copper wire. As it has a resistance of 0.3133 ohms per 1,000 foot length. To equal the same resistance and match the previous current flow, a massive length of 3,348,000 feet needs to be used. This length of wire will weigh 335,469.6 pounds which is 16.77 tons. The 10-foot interior diameter coil, 8.32 feet tall, wound with this wire will have about 90,000 turns. If 100 volts DC is now connected across the coil, the same 95 milliamp current will flow with an input power of 9.5 watts, the same as before. But due to the massively larger coil, it has a magnetic field of 23.7 Gauss, which is 1,905 times larger than the previous coil, and with 116 Joules of energy stored in the magnetic field. This is a phenomenal 8,000,000 times more energy than in the 40-gauge coil of the previous example. A phenomenally larger current flow would now occur if the current input was stopped and the coil shorted out, as that would generate an inductance of 25,700 Henries which is more than eight million times the inductance of the previous coil:

Joseph then built a smaller version of his design, as shown here:

this prototype used 5-gauge insulated copper wire weighing 4,200 pounds and 300 pounds of 30-gauge copper wire wound over the 5-gauge winding, and a massive 4-foot long, 20-inch diameter permanent

magnet of some 600 pounds in weight. The coil was wound with an inner diameter of 4-feet and a height of about 3-feet, wound on a fibreglass tube. The overall weight was about 5,000 pounds.

Everybody who was it was asked: "Based on your expertise, how much power would be necessary to simply operate this device mechanically?". Answers ranged from 200 watts to 1,000 watts. On learning that it had an air-cored coil, other skilled individuals stated that in their expert opinion, the unit would be highly inefficient since it contained no iron core. However, from the design information already presented here, it can be shown that the actual necessary power input is less than 1.5 watts providing a power output far in excess of 100%.

Dr. Roger Hastings, Principle Physicist at Sperry Univac Corporation and former Associate Professor of Physics at North Dakota State University, tested this prototype and showed that it had an 800% efficiency – that is a Coefficient of Performance of 8.0 which is impressive. In addition, Dr Hastings estimated that with a 1.5 watt power input, the back emf exceeded 80,000 watts. In operation, the 600-pound, hand-made magnet rotates at just 200 rpm.

Joseph's patent which is in the Appendix, indicates four different ways of implementing his design principles. It is very clear that Joseph has proved his point by producing and constructing a device which Oliver Lorentz considered to be impossible, thanks to his throwing out the free-energy sections of Maxwell's equations. Joseph Newman has clearly earned our respect.

You can see J L Naudin's builds and tests of small models at <http://jnaudin.free.fr/html/qm11bp.htm>.

Daniel Cook's Motionless Generator.

In 1871, Daniel Cook obtained US Patent 119,825 for "An Improvement In Induction Coils". It is by no means obvious how the device described could possibly operate, and it has been suggested that the patent information is incomplete, having been edited at a later date. But as I have no direct evidence that it does not, or cannot, operate, it is shown here. Interestingly, the highly-respected Dr Harold Aspden considers this a very serious piece of equipment, operating as paired cross-linked capacitors, and his opinion carries very considerable weight.

It is a very simple device which could be interesting to test, especially as it does not involve any electronics or complicated construction. The patent can be summarised as follows:

My invention relates to the combination of two or more, simple or compound, helical coils with iron cores or magnets, in such a manner as to produce a constant electric current without the aid of a battery.

Fig.1 represents the different parts of a compound helical coil and iron core.

Fig.2 is a perspective view of my invention.

In carrying out my invention, I do not confine myself to any particular mode of coil construction or to any particular size of wire, observing only that the quantity of wire in the various coils must be sufficient to produce the required result; also, the material used to insulate the wires must be suitable for producing the required result. However, I generally prefer to use the same size of wire in the construction of both simple and compound coils.

When constructing simple coils, to produce the required voltage and current, it is desirable to use a long iron core as shown as **A** in **Fig.1**. This iron core may be two, three or even six feet in length, and two, three or more inches in diameter. The coil should be wound from good quality copper wire, insulated with silk or

shellac. The iron core **A** may be a solid bar or a bundle of separate iron wires, the latter giving better results and providing more current for any given wire diameter. While the wire may be fine or coarse, I prefer to use No. 16 or even heavier wire, as the power output is in proportion to the length and diameter of the wire.

When using compound coils, it is preferable in some cases to use a small wire, say, No. 30 or even less, for the primary coil, and No. 16 or even larger for the secondary coil. With this combination, the initial secondary current of the primary coil being very small in comparison to the terminal secondary current of the secondary coil, offers little resistance to the terminal secondary, hence a quicker action is obtained. Alternatively, the primary coil may be of uninsulated wire coiled into a solid helix, being insulated only between the coils, in which case there is little or no opposing initial secondary current.

Helically wound coils alone with large quantities of wire will produce similar results. A ribbon spiral may be substituted for the secondary coil **C**, say, of three, six, twelve or twenty-four inches in width and of any convenient length, but always of sufficient length to raise its output current to the level necessary to sustain itself through its action on the primary coil **B**. In the use of compound coils, it is important that the secondary coil should be wound in the same direction as the primary coil, and the primary and secondary coils be cross-connected as shown in **Fig.2**. The action will then be as follows:

The secondary current of the secondary coil **C**, will circulate through the opposite primary coil **B**, while at the same instant, a secondary current from the primary coil **B** will be generated and circulate through the opposite secondary coil **C**, both currents flowing in the same direction in the opposite coils **B** and **C**, producing a combined magnetic action on the iron core **A** in the centre. The opposing initial secondary currents of the two coils **B** and **C** being overpowered, do not show in the main circuit **D** of the device, there being eight distinct currents developed in the action of one entire circuit of the two pairs of coils, two terminal and two initial secondary currents to each pair of coils, the four initial secondaries constantly opposing the circulation of the four terminal secondary currents, but the initial secondaries being of much lower voltage and current than those of the terminal secondary, are overcome, leaving a sufficient surplus terminal power to overcome the resistance of the primary wire and charge the bar **A** to the degree needed to reproduce itself in the opposite secondary coil. By this means, a constant current is kept flowing in all of the coils.

These coils may be constructed using 500 feet to 1,000 feet or more for each of the primary and secondary coils. The longer, and better insulated the wire, the greater is the power obtained from the device. The larger the wire diameter, the greater the current obtained.

If only single coils are to be used, it is preferable to have a wire length of 1,000 feet or more in each coil. The action is the same as with the compound coils, but only four currents are produced: two initial and two terminal currents, the latter flowing constantly in the same direction - in effect, there being only one current in the same direction.

The action in the coils may be started by using a permanent magnet, an electromagnet or by pulsing an extra coil wound around the outside of one of the coils of the device. If the load circuit is broken for any reason, the current stops immediately. It is then necessary to perform the start-up procedure again to get the device restarted. This can be overcome by permanently connecting a resistor across the terminal of the load so that if the load circuit is broken, the device can continue under very much reduced current until the load is restored. By this means, the device becomes the direct equivalent of a battery.

A rheostat **D** may be introduced into the main circuit to limit the current and prevent the overheating of the coils through the drawing of excessive amounts of current. The iron cores may also be used for producing electromagnetic motion when the device is operating.

Note: Interesting replication attempts are shown at <http://www.overunity.com/index.php/topic,2630.0.html>.

Michael Eskeli's "No Work" Generator.

One of the greatest expenses for many families is the cost of heating or cooling a home. Any device which can help with this task is definitely welcome. Michael Eskeli has produced several most interesting designs which may have been overlooked due to lack of emphasis of what they do.

Normally, a central heating system uses an expensive method of heating a liquid, typically oil, which is then pumped through radiators around the building by a low energy pump. The vast majority of the cost is in heating, typically, a furnace and very little is spent on moving the heated liquid through the radiators. In this

design from Michael, the cost of the heating is zero, and all that is left is a low-power (quarter to half horsepower) input, needed for spinning a rotor against the friction of its bearings and stuffing box.

As this seems impossible, a little very technical explanation is given here. This information has come from the web site of Scott Robertson at <http://www.aircaraccess.com/> with his kind permission. In broad outline, the device comprises of a disc-shaped housing with a closely-fitting rotor spinning inside it. A gas under pressure and a liquid under pressure are both fed into the device and they intermingle in a pulsating sequence which alternately compresses and releases the pressure on both fluids. This heats both fluids very effectively, and most interestingly, without the use of any user-supplied heating power and without the use of any heating fuel. This next paragraph is for Engineers, so if you don't understand it, then just ignore it, as the important thing is to understand what the device does, rather than exactly how it does it.

The Heat-Pump Work Cycle: The example diagram above shows the sequence of events caused by the rotation of the disc inside the device housing. This “**Pressure / Enthalpy**” or “**Pressure / Internal-Energy**” diagram shows the pressures and temperatures during a single pressure cycle of the device. Using nitrogen as the gas, the cycle starts at point “1” which has a pressure of 150 psi and a temperature of sixty degrees F. A pressure wave now hits the mix of nitrogen and the liquid. This pressure wave moves us to point “2” where the pressure has been boosted to 540 psi which raises the temperature to 280 degrees F.

Moving to point “3” is where the wanted heat is passed throughout the gas and the liquid (performing the heating task which is the whole object of the exercise), even though the pressure is maintained, so at point “3” there is a pressure of 540 psi and a temperature of 138 degrees F. Next, comes a major drop in pressure, taking us to point “4” pulling the temperature down to below freezing: 250 psi at just 4 degrees F. At point “5” the pressure is dropped further to 150 psi, still at 4 degrees F. Point “6” takes us to 250 psi at 60 degrees F from where the cycle takes us back to point “1”, and the sequence starts all over again.

The compression takes place on leg 1 to 2 and leg 5 to 6. The actual amounts are 53.2 and 13.5 respectively, giving a **Compression Total** of **66.7 B/lb**.

The expansion takes place on leg 3 to 4, leg 4 to 5, and leg 6 to 1. The actual amounts are 31.6, 16.6 and 18.7 respectively, giving an **Expansion Total** of **67.0 B/lb**.

As these two are virtually identical, the overall result of a complete cycle is effectively **work-free**.

This work cycle can be readily performed by the **Centrifuge-Type Heat Pump**. This is a unit which has only one moving part, the rotor, the working fluid, such as nitrogen, is sealed in with the rotor and circulates in passages in the rotor. The circulation of the working fluid inside the rotor is accomplished by density control alone, in accordance with the work-cycle shown above, and **there is no work input to the working fluid from the rotor shaft**. Thus the work input for the heat transfer is nil, and a work-free heat pump results.

In the diagram shown below, an axial cross-section and an end view with sections removed, shows a typical heat pump rotor suitable for use with the work-cycle discussed above.

In the diagram, **10** is the heated-fluid heat exchanger, **11** is the heat-supply heat exchanger in two parts, and **12** are the vanes in passages which return the working fluid from the periphery to the centre of the disc. The work cycle process is of the non-flow type for the working fluid in this rotor, and this provides higher performance than that in the example shown above.

Centrifuge-type Heat Pump

The fluid to be heated is usually a liquid, such as water, which enters and leaves the rotor via the rotor shaft. Similarly, the heat-supply fluid circulating through heat exchanger **11**, is a liquid which enters and leaves via rotor shaft passages.

The work-free heat pump obviously has many uses. One such use is in heating all types of buildings and homes, resulting in cost-free heating, since no fuel is needed, and the power usage is nearly nil. In the heat pump shown above, power is needed to drive the rotor against friction which may require a quarter to half horsepower motor.

Another use is in power generation, resulting in cost-free power since the unit uses no fuel, the energy source being either ambient air, or water from some natural source. (Attached turbine generates the power; part of this is used to overcome the heat pump friction loss and the remainder is available for generation of electricity). Further uses are in portable power and transportation vehicles, etc.

The apparatus and methods and work cycles are patented. For basic heat pump, see US Patent 3,926,010 and Canadian Patent 984,827.

Michael Eskeli.

Here is one of Michael's many patents:

US Patent 3,650,636

21st March 1972

Inventor: Michael Eskeli

ROTARY GAS COMPRESSOR

ABSTRACT

Method and apparatus for a compressor for compressing air, gases and vapours isothermally using a liquid stream to compress the gas; the liquid issuing from an impeller intermittently, with the gas being entrained between these liquid pulses and compressed by the liquid; the liquid having high kinetic energy when leaving the impeller and in slowing the kinetic energy is converted to pressure for both the liquid and entrained gas.

Also, this compressor may be used advantageously to compress vapours, wherein the liquid is the same fluid as the gas, in which case condensation of the gas to the liquid occurs, and work of compression is reduced.

BACKGROUND OF THE INVENTION

This invention relates generally to devices for compressing gases, air and vapours, in which a liquid is in intimate contact with the gas or vapour to be compressed.

DESCRIPTION OF PRIOR ART

There are numerous devices and machines available for compressing a gas or a vapour. In some of these machines a liquid is rotated inside an eccentric casing, so that the machine rotor will cause the liquid to pulsate and the space between the rotor blades is increased or decreased, and this variation compresses the gas. These machines are called liquid piston type machines. Another device is the jet ejector compressor, where a stream of liquid or gas is used to entrain the gas or vapour to be compressed, and the kinetic energy of the stream is converted in a diverging nozzle to a pressure.

The main disadvantage of the liquid piston type machine is its poor efficiency, since the liquid is rotated in the machine and requires relatively large power input for compressing the gas. In the ejector compressor, the velocity of the liquid stream is limited and it entrains poorly of any gas; therefore the efficiency of the device is very poor. The available kinetic energy in the liquid stream is high, but due to poor entrainment of the gas by the liquid, results for the device are poor.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig.1 is an end view of the compressor casing, showing the exterior.

Fig.2 is a side view and a section of the casing and the impeller of the compressor.

Fig.3 is a side view and a section of the impeller, and

Fig.4 is an end view of the impeller, showing the fluid passages.

DESCRIPTION OF PREFERRED EMBODIMENTS

It is an object of this invention to provide a method and a device for compressing gases or vapours essentially isothermally in which the kinetic energy contained by a liquid stream is used to compress said gas to a higher pressure where the liquid in slowing in speed will increase its pressure and increase the

pressure of the gas being entrained in it. Also, it is an object of this invention to provide a method and a device in which the gas may be partially or fully be condensed in the liquid stream thereby lowering the work of compression; this occurring when the gas or vapour being compressed is the same fluid as the liquid; that is, the gas being compressed is the vapour phase of the fluid, and the liquid being used for as the motive fluid is the liquid phase of the fluid.

Referring to **Fig.1**, there is shown an end view of the compressor, where **10** is the compressor casing, **11** is the liquid inlet, **12** is the gas or vapour inlet, and **13** is the outlet.

In **Fig.2**, a side view of the compressor is shown. The impeller **22** is rotated by shaft **28**, supported by bearings and sealed by packing **23** and stuffing box **24**. Alternately a mechanical seal could be used. The liquid that is used as the motive fluid enters through opening **11**, passes through the impeller **22** and leaves the impeller at a high velocity and entering the throat section **21** and from there the diffuser section **29** in the casing **10**. After leaving the diffuser at a higher pressure, and at a lower velocity, the gas and liquid mixture is collected in annular space **30**, and from there passes out through opening **13**. The liquid entrains gas from annular space **31**, and the gas enters the annular space from outside through opening **12**.

In **Fig.3**, the impeller **22** is shown in more detail, where **38** is the fluid passage, and **36** is the opening for the drive shaft.

In **Fig.4**, the impeller is shown, with **22** being the impeller and **38** being the fluid passage.

In operation, the compressor functions in a manner similar to a jet ejector compressor. A motive fluid is accelerated in a passage in the impeller to a high velocity; this corresponds to the motive fluid nozzle in a jet ejector. However, the fluid stream issuing from the impeller, when it rotates, is not continuous as seen by the compressor casing, since in this particular instance, the impeller has four fluid passages, with solid material between them. Therefore, the flow from impeller, as seen by the compressor casing, is pulsating, with empty spaces between the high speed liquid; these empty spaces being filled by the gas from the annular spaces, item **31**, **Fig.2**, and the gas being rapidly moved with the liquid to the outer annular space **30**, and from there to discharge. This pulsating action improves the entrainment of the gas by the liquid, and more fully utilises the kinetic energy available in the liquid stream.

The sizing of the fluid passages and the calculations related to them, are fully described in thermodynamics literature for jet ejectors and for steam injectors. The space of the passage **38** in **Fig.3**, would be either converging for liquids that do not vaporise when leaving the passage; or the passage could be diverging at its outlet for fluids which will vaporise either partially or fully when leaving the passage. Of the non-vaporising liquids, water would be an example, and of the partially vaporising types, butane would be an example, both at atmospheric temperatures, and at low pressures. As illustrated in **Figs. 2-4**, passageways **38** comprise a converging section nearest the centre of the impeller but are at least non-converging at the discharge section. Preferably, the at least non-converging section is a diverging section for better taking advantage of the energy available in the motive fluid to achieve higher exit velocities.

The fluid passages shown in **Fig.4**, item **38**, can be radial as illustrated, or be forward or backward curved, depending on the fluid used. Also, the throat section **21**, of **Fig.2**, may have vanes of proper shape to prevent circular motion of the fluid after it leaves the impeller. Vanes of this type are commonly used in

turbines and pumps and so are not described here. There are four fluid passages shown in **Fig.4**, but this number will be determined when calculations are made for the size of the passages, and the frequency of pulses of liquid required to maintain suitable pressure and volume relationships inside the compressor; also, the rotational speed of the impeller would enter into these calculations.

Normally, the amount of liquid is large when compared to the amount of gas or vapour. Therefore, when compressing a gas, the heat of compression from the gas is transferred to the liquid, resulting in a temperature increase of the liquid, as well as of the gas. This temperature increase is much less than it would be for the gas alone, resulting in nearly isothermal compression, and therefore reduced work of compression, as compared to isentropic compression which is often used in rotary compressors. Also, if a liquid that will expand in the impeller is used, with an expanding fluid passage, the temperature of the motive fluid is lowered, and the fluid velocity greatly increased, resulting in much better efficiency for the compressor; this is similar to the function of converging-diverging diverging nozzles in jet ejectors.

The operation of the compressor may be inferred from the above descriptive matter. A liquid source is connected to the impeller inlet **Fig.1, 11** and a gas or vapour source is connected to the gas inlet **Fig.1, 12**. Discharge from the compressor is from **Fig.1, 13**. A suitable power source, such as an electric motor, is connected to shaft **Fig.2, 28**, causing the shaft to rotate. The liquid is accelerated by the action of the impeller, and as it passes through the annular space **Fig.2, 31** in a pulsating flow, it entrains the gas and carries it to annular space **30**, from where it discharges.

Materials of construction for the compressor would be similar to those used to make pumps for pumping liquids. Cast iron, steel, bronze, brass, stainless steel and various plastics could be used.

CLAIMS

What is claimed new is as follows

1. A machine for compressing gaseous fluid and having the major components of:
2. The machine of claim 1 wherein said at least non-converging section is diverging.

The Work of Karl Schappeller.

There have been a number of quite outstanding men who have had great insight as to how the universe is and how it operates. One of these is Karl Schappeller who is virtually unknown. One of the reasons for this is the fact that publicising his work has been strongly opposed by people who do not want his understanding to become widely known. One device produced by Karl in order to prove that his understanding of things was correct, produced substantial amounts of excess energy, and while I do not know of anybody who has replicated his device, I am including here, a short presentation on the subject, written by Henry Stevens and the book by Cyril Davson can be downloaded from <http://www.free-energy-info.tuks.nl/Davson.pdf> and read in full.

In the presentation by Henry Stevens, he mentions UFOs or flying discs. There has been a propaganda campaign waged against the general public for more than fifty years now, with the objective of persuading people that "UFOs" are not real, and if they were, then they would be the vehicles of "little green men". This campaign has been remarkably effective and members of the public in general will immediately dismiss flying discs as being "impossible" and not something which any sane person would consider for a moment. This attitude is based on an almost total lack of knowledge of the facts. There are at this time, large numbers of flying discs, built by humans and capable of spectacular flight abilities. There are two varieties: those which need the atmosphere to operate and those which don't.

If you feel that this is a "load of rubbish" then take a look at the following US patents:

This small selection of forty-six patents is restricted to just those which have the well-known circular “flying saucer” shape. Do you seriously think that not a single one of these patents had a test prototype which flew or that they were all piloted by “little green men”?

I have no interest in flying machines which need an atmosphere as they are just advanced versions of conventional aircraft. In the early 1900s, Nikola Tesla designed and built what he described as his “flying machine”. This was a small device without wings and which ‘flew’ without the use of a fuel. This design of Tesla’s was taken by the Germans and during World War II, developed and experimented with. After the war, it was taken to the USA and developed further at Groome Lake, and at this time, the US, UK, Canadian and Russian governments have got large working copies which they keep as secret as they possibly can. One major cover story is that these craft belong to “extraterrestrials” who have such an advanced level of technology that we will never be able to understand it. It is a good story, as it is not possible to disprove it. If

you want a good deal of specific information on this, then read "The Hunt for Zero Point" by Janes researcher and writer Nick Cook.

While I have no particular interest in electrogravitic propulsion (or "anti-gravity" as it is popularly known and incorrectly termed) if the subject interests you then take a look at the YouTube video sequence of Stan Deyo who was one of the people who developed electrogravitic propulsion for an international group, several decades ago. Stan explains "gravity" as being the product of spin affecting the space-time continuum.

The Karl Schappeller Device

Author: Henry Stevens

Was the Schappeller device an engine used in German field propulsion saucers? This is a possibility. Because so little has been reported about this device in the English language, the following is a report describing Karl Schappeller and his device in some detail.

Karl Schappeller (1875-1947) literally went from being born in poor-house to owning a castle during his lifetime. His economic success was mirrored in his experiments in energy as a lay-scientist, culminating in the invention of a free-energy device which attracted considerable attention around 1930. Schappeller made no secret of his invention and actively sought private financing to manufacture and distribute the results of his research. He was in touch with financial concerns and he even spoke with a representative of the British Admiralty concerning the utilisation of his device to power Royal Navy's ships (1).

At this time, 1930, the device was somehow appropriated and further worked upon by a governmental organisation of the German Weimar Republic, the Reichsarbeitsgemeinschaft or Reich Works Association (RAG). At least one aim of the RAG was to make Germany self-sufficient in energy production. Specifically, they published their intentions to utilise many Schappeller devices in a system of broadcast energy distribution throughout Germany which would result in the entire elimination of the electrical grid (2). As we know, Adolf Hitler assumed power three years later and for strategic reasons, he was also very interested in making Germany independent of foreign sources of energy. It is known that political and scientific structures were set up to work on the energy problem as evidenced later by the synthesising of gasoline and oil products from coal by the 3rd Reich. One of these political and scientific structures was contained within the SS and it is known that Karl Schappeller actually met with SS Reichsfueher Heinrich Himmler in Vienna in 1933 (3).

Left: Inventor Karl Schappeller **Right:** Karl Schappeller's Device. **A.** Steel outer casing. **B.** Special ceramic

lining in which tubes are embedded. **C.** Hollow centre, filled by glowing magnetism when in operation.
D. Tubes, circuit and earthing.

Fortunately, there are good descriptions of the Schappeller device upon which to draw in both German and English. Per Vrill-Mythos is a complete discussion of Schappeller, his device, the history and the controversy surrounding it. "Vrill, Die Kosmische Urkraft Wiedergeburt von Atlantis" and "Weltdynamismus Streifzuege durch technisches Neuland an Hand von biologischen Symbolen" represent an attempt by the RAG to popularise their ideas in booklet form. Finally, British electrical and mechanical engineer, Cyril W. Davson, visited Karl Schappeller in Austria and spent three years learning of his device and his theory before the Second World War. Davson's descriptive book, "The Physics of the Primary State of Matter", was written in 1955, after the war and the death of Schappeller.

Before describing the device itself it should be understood that Schappeller and all writing about his device believe that the energy-source being tapped is aether energy, sometimes called "Raumkraft" or "Raumenergie", that is space-energy (4)(5)(6). This device was also said to be capable of, perhaps with some tuning, emitting aether as a radiant energy (7). The physics of aether energy is described by Davson as "primary physics" as opposed to "conventional physics" which he believed could only be considered to be a secondary, derivative understanding.

Aether Theory

For readers who have never heard of "aether", perhaps the simplest explanation for aether physics is that of the late Dr. Hans A. Nieper (7) entitled "Revolution in Technology, Medicine and Society". Aether could be thought of as an energy source emanating from everywhere equally at once. The universe could be considered, as is often said, to be "a sea of energy". It forms a background of energy everywhere, and since it is everywhere all the time, it is difficult make independent measurement of it. This aether energy is in constant motion. All energy is radiant energy, according to this theory. This can easily be appreciated as to electromagnetic radiation but it is also true of that very elusive thing called gravity. Newton described the effects of gravity but he never told us exactly what it was. Dr. Nieper tells us that gravity is really a push, and not a pull. Gravity is acceleration and is caused by the aether field. Again, all energy is radiant-energy whose fundamental basis is aether radiation.

From the aforementioned book by Dr. Nieper:

In addition, Nieper established the axiom that, "all natural accelerations can be attributed to a single unified basic principle, namely, the interception (or braking) of a field energy penetrating from the outside (gravity acceleration, magnetic, electromagnetic, electrostatic and radiesthetic acceleration)".

In trying to explain aether, it might be thought of as an all-pervasive liquid, occupying all of space. This liquid concept is useful because a liquid can not be compressed but can only transfer the energy attempting to compress it from one location to another. This is how the brakes of a vehicle work. The driver presses the brake pedal when he wants to slow down or stop. The plunger of the brake pedal attempts to compress the liquid in the master cylinder. The master cylinder is connected to each wheel by metal tubes full of liquid. When pressure is put on the master cylinder by the driver it is transmitted to each of the four wheel cylinders full of the same fluid which transmits the force, moving the brake mechanism, slowing the wheels of the vehicle.

In a similar way, the aether serves to transmit energy through this "non-compressible" quality. In a primary electric coil and secondary electric coil, for instance, induction in the secondary does not take place directly from the primary as is now said by current physics, but instead, the induction between the two windings is due to the aether field. This concept of the energy transfer function of the aether field is also expressed by Davson.

Using this perspective, that all energy is radiation, the braking of aether radiation, that is the slowing down or stopping of this radiation, can cause a transfer to other forms of energy. The word "energy" means the entire electromagnetic spectrum. That includes, electric, magnetic and electrostatic fields. This means heat. This also means gravity. Again, gravity is the primary radiation of the aether field. It radiates from every point in the universe equally.

This concept seems ridiculous until it is given some thought. One might ask: "How can gravity be a push when we know better?" After all, things fall to earth, don't they? The answer is that the effects which we feel and call "gravity" are due to aether shielding. Aether radiation can be braked, that is slowed down and absorbed by mass. It is then re-radiated or converted into mass. It is re-emitted as slower aether radiation

or even as heat. Some of it can, and is, converted into mass inside a planet. If there is a loss of aether radiation, then there is shielding. Thus, a planet would shield from this radiation in one direction. That direction is always toward its centre which is the direction of greatest mass and that is what we describe as "down". This is simply the area which contains the maximum amount of shielding. In all other directions the aether radiation continues to exert its push on us. The area of minimum shielding is directly opposite the area of maximum shielding, so things fall (or more correctly are accelerated or "pushed") towards the earth.

Think about this for a minute. Being in deep space is rather like being underwater. Underwater, the pressure at all points is so similar that we feel weightless. We are weightless in deep space because the aether field exerts a push on us from all directions equally. In space, the nearer one gets to a large body the stronger the push is from the opposite direction since the body shields or converts the aether radiation. The result of this thinking is a mechanism totally different from "gravity" as we know it but appearing as exactly the same observed phenomena.

The beauty of this aether theory of gravity is that gravity functions like every other form of radiation. Its underlying cause, aether radiation, can be converted to mass or, in certain circumstances, re-radiated or converted to other forms of energy. No Unified Field Theory is necessary. The aether field **is** the unified field. Further, there is no need to look for something separate called "anti-gravity". If gravity is a push then it is all anti-gravity. All we have to do to make a UFO, is to find this particular gravity frequency and find out how to generate it.

Aether physics was a lost physics. Physics was hijacked early in the 20th Century by the alleged results of the Michelson-Morley experiment. This experiment assumed that "aether" was matter. There is some confusion here. We know now that particles moving near the speed of light are measured as waves, that is energy, rather than as matter. Nevertheless, aether theory has been discredited among physicists who, in turn, discredit others who raise the subject. It is only through the efforts of "free-energy devices" and free-energy researchers, that this knowledge is being returned to us. Without this aether theory, the reason these devices work cannot be explained at all. Rejection of aether theory allows these devices to be dismissed as "theoretically impossible" and so "fraudulent" by implication. They are marginalised and dismissed as "perpetual-motion devices". According to established physics, perpetual-motion devices violate the physical laws of conservation of energy. Without an aether theory as an explanation, they do violate the laws of conservation of energy and so their detractors are able to simply dismiss them out of hand. The simple fact that some of these free-energy devices actually work, does not seem to bother these scientists in the least. Rather than change the theory to accommodate the observed facts, the facts are ignored and substituted by dogma. Whether we like it or not, we are living in an energy Dark Age.

Instead of aether theory, we have all been led to focus upon Einstein and his Theories of Relativity. Two or three generations of scientists have wasted themselves on "trying to prove Einstein right". This misguided thinking has resulted in stagnation. One need go no further than the many "free-energy" devices which have arisen to the level of notice in spite of accepted scientific theory to see that this statement is true.

Needless to say, German scientists of the Nazi period laboured under no such illusions. They never abandoned aether physics. This was the fundamental reason why field propulsion UFOs were first developed in Germany. After the Second World War two different sciences developed, both called "Physics". One was the relativity-based concept taught in schools, while the second, more esoteric type, was used secretly, by the secret government, for deep "black projects".

Structure of the Schappeller Device

According to Davson's description, upon which we will rely, the Schappeller device is really composed of two separate units, the rotor and the stator. The stator is constructed as follows: Its surface is round or ball-shaped, being composed of two half-shells of steel. These half-shells contain the internal structure and are airtight. Attached at the "pole" of each half-shell is an iron bar-magnet, most of which is positioned inside the sphere. This means that the bulk of each magnet is inside the steel ball, one opposite the other. There is a space between the two bar magnets at the very centre of the sphere.

An Insulating ceramic material, is placed on the inside of the steel ball, leaving a hollow central area. Within this hollow area, and around the space between the magnets, are two coils are mounted. These start at the pole of the bar magnet and finish at the centre of the sphere, with a connection leading out of the sphere to the rotor. These coils are wound using a hollow copper tube filled with a special, secret substance called the "electret". Upon leaving the sphere, the electret-filled copper tubes are replaced by conventional copper wire. An electrical connection is made from the outside surface of one pole to one pole of a special type of

battery which is grounded at the other pole or, alternatively, to a special device called an "Ur-machine" which will be discussed later.

This electret is a permanent magnet within the sphere. This type of magnetism is not identical with ferromagnetism or electromagnetism, it is much stronger (8). The actual composition of Schappeller's electret remains a secret, but another electret has been made by Professor Mototaro Eguchi. It consists of carnauba wax and resin, perhaps also containing some beeswax. It was kept in a strong electric field while baking slowly until it solidified. For purposes of the production of Schappeller spheres, a complete electret manufacturing plant would have to be set up, which has no parallel in present science (9).

Before being set into operation, all the air is pumped out of the hollow core of the sphere. This whole ball is mounted on a swivel mechanism so that the poles can be moved from the vertical to the horizontal. The stator is not attached to the rotor. The stator can function without the rotor and the stator is capable of producing electrical energy without the rotor. The rotor could also be used to generate additional electrical energy.

The rotor consists of a steel wheel of special design fixed on the shaft to be driven, and surrounded on its outer surface by magnets which are attracted and repelled by the force of the stator. The copper wire attached to the internal electret-filled copper tubing, runs through this wheel and supplies electric power to the magnets. The magnets are hollow and filled with the same electret. There is always an odd number of magnets.

A variant of this rotor comes to us from Taeufer, who refers to this further development as the "Ur-Machine". This machine is composed of six sphere units as described above, five revolving around a sixth one which is positioned either above or below the plane of the other revolving spheres. A seventh unit would be employed to rotate the five rotating spheres and so would be offset, and not attached to the others. The five rotating spheres would charge the sixth stationary sphere. The sixth and seventh spheres would function as an anode and cathode and so ground the unit. The Ur-machine could be used to activate other spheres instead of a battery-earthing procedure (10).

As a prime mover, an engine, the rotor would be used to turn a drive shaft. The stator would be offset, that is, moved off centre in relation to the rotor. Schappeller worked out various angles of efficiency (11). The drive shaft could be used to power any number of machine applications such as, for instance, the propellers of a ship.

Means of Operation

The device is started through a connection to a totally unique battery and a connection to the earth (12). A specific excitation impulse must be given to the device (13). This electric impulse is conducted through the iron magnet and jumps the gap in the centre of the sphere to the other iron magnet.

What occurred then sets this device apart from all others. In the vacuum of the sphere, in the centre space between the two bar magnets a field of "glowing magnetism" is set up. This glowing magnetism is something entirely unique. It is recognised as a magnetic field, but much more powerful and unlike any magnetic field produced by an iron bar or an electric coil. Once the initial input had been made to start the device, the battery and ground can be disconnected. The device then continues to operate on its own (14).

For an understanding of what is really happening here we have to consider the bar magnet. We think of a bar of iron with two poles, one positive and one negative or perhaps one north pole and one south pole. But there are really three components to the bar magnet. There are the two poles and the neutral zone between the poles. If we cut the magnet in half we get two new poles. For the Schappeller device, this neutral zone is very important. Imagine a bar magnet running through the vertical axis of the ball. Then imagine the centre section cut out. We now have a north pole at the top of the ball, a south pole at the bottom of the ball just as we do with the planet Earth. In the centre we have a missing section with a south pole, opposing the north pole at the top of the ball and, likewise, a north pole opposite the south pole at the bottom of the ball. We have now four poles and a split bar magnet with a gap in its centre section.

It is this gap in the centre where Schappeller's "glowing magnetism" is generated by grounding, that is, charging the device via a special battery and an earth connection. This glowing magnetism is the mystery. Davson cites Schappeller's calculations and gives this form of magnetism as being a thousand times more powerful than that produced by present magnetism (15). He also states that in this form of magnetism the electricity is stationary while the magnetism is radiated (16).

To state this again, Davson contends throughout his book that this glowing magnetism is not found in secondary physics, that is, in modern physics, and that this glowing magnetism is a manifestation of primary physics. As a phenomenon of primary physics, it is responsible for, and can generate, heat, electricity and magnetism.

After initial stimulation and in a state of glowing magnetism, no further input of energy is needed from the battery. The device is able to draw in energy to it directly from the surrounding aether, bind this energy though its magnetic electret material, that is the filling in the hollow copper coils of the internal coil, and then re-radiate energy producing heat, electricity, magnetism or mechanical work depending upon the application.

Stated another way, this is an implosion device and it is described as such (17) (18). Unlike the Schauburger device which is associated with the word implosion, the Schappeller device operates purely at the energetic level. Energy is drawn towards the centre, through the magnets, into the field of glowing magnetism, and then radiated outward.

My first explanation for this output of radiant energy involves the concept of the Bloch Wall. A Bloch Wall is defined by Van Norstrand's Scientific Encyclopedia, 1958 edition, pages 201 and 202, as: "This is a transition layer between adjacent ferromagnetic domains magnetised in different directions. The wall has a finite thickness of a few hundred lattice constants, as it is energetically preferable for the spin directions to change slowly from one orientation to another, going through the wall rather than to have an abrupt discontinuity" (18).

In electromagnetics the Bloch Wall is external to the hardware itself. It is the point of division of the circling vortex, or spin, of the electronic magnetic energies of the north and south poles. The negative north pole magnetism spins to the left while the positive south pole spins to the right. Energy is being conducted into the Schappeller device through the un-insulated poles and being conducted and spun on its way to the centre of the unit. The point of zero magnetism, no spin and magnetic reversal, where the two spin fields join, is the Bloch Wall (19).

Bloch Wall, a gravity wave source as a function of the electromagnetic spectrum?
(Dr. Richard Le Fors Clark)

Oscillating circuit. Charged capacitor (electric field) discharges, current carried through insulated wire to charge coil (magnetic field) which discharges, charging capacitor.
Oscillating electric and magnetic fields yield electromagnetic waves.

The Block Wall radiates energy. Remember, if energy is coming in then it must be going out. The Bloch Wall may generate radio, radar and other electromagnetic frequencies but what is most interesting is that it is actually able to radiate gravity as according to Dr. Richard Le Fores Clark. According to this interpretation, the conjunction of two dipolar generated force-field vectors, a quadropole force field or gravity is generated according to Dr. Clark. Gravity being a quadropole source, it radiates in a circular, 360° , pattern of two cycles. Dr. Clark has fixed the point of emission as below that of radar and above infrared at 10^{12} Hz (20). Dr. Richard Le Fors Clark believes that gravity is a radiation (20) and so it is a "push".

Another Opinion

In late 2001, I wrote a magazine article on the Schappeller device (20) which contained most of the material described above. In that article, I requested alternative explanations for the Schappeller device. I received a letter from Mr. Michael Watson, BSc, Chartered Physicist and Member of the Institute of Physics in the United Kingdom. But there was something in Mr. Watson's background even more impressive than his professional credentials. Cyril W. Davson was a family friend whom Mr. Watson knew well in his youth and with whom he had discussed Schappeller and his ideas at some length on many occasions. In Mr. Watson's letter was a brief summary of Schappeller's theory in which he cut through most of the confusing terminology.

This summary is important for a couple of reasons. Mr. Watson's summary of Schappeller's aether theory as described by Davson dovetails nicely into the ideas of Schauberger yet seems to allow for Tesla's experimental results on aether as explained by Bill Lyne. The following is what I learned from Mr. Watson's letter:

Most of us have heard of the two Laws of Thermodynamics. These are laws of heat. The First Law of Thermodynamics states that energy is conserved, meaning that the total amount of energy in the universe always remains the same. This is no surprise for most of us and it is not the real concern here.

What is of concern is the Second Law of Thermodynamics which discusses heat and entropy. The word "entropy" might be thought of as a state of randomness or chaos. Negative entropy would then mean movement toward a less random or more ordered state of any particular thing. If we apply this to a system, then entropy tends to increase until the system breaks down in utter chaos. This will occur unless the system is re-charged with additional outside energy. A concrete example of this might be helpful:

Imagine a new car just coming off an assembly line. It has taken a great deal of energy to find, refine, forge, weld, and paint the metal parts of this car. This same concept also applies to all the other components of the car. This energy and organisation constitute a highly organised state, or, in other words, a state of negative entropy.

What happens next illustrates entropy. The car is purchased. Whether it is driven hard or just sits in the

garage does not matter in the long run because what happens to the car is that it starts to fall apart. This change may be small at first and may only occur at the molecular level, but it occurs nevertheless. The engine, transmission, paint, rubber, electronics, etc. all will fail with time. Even if the car just sits in the garage, in a thousand years the metal will eventually oxidise. Finally, the car rusts away forming a reddish brown heap. This is exactly the opposite of the organisation and energy used to put the car together. This disorganisation is entropy. The only thing which will reverse this, as we all know, are additional inputs of energy by the owner in the form of maintenance and repairs.

All things in a relative state of order move toward a state of disorder. In terms of heat, heat will always flow into a colder place from a warmer place. When something is heated there is a rise in its entropy. With increasing heat its molecules move faster and faster in random chaos, just as a bomb does when it explodes. Increasing heat means increasing randomness and chaos which is entropy. Cold, then, can be seen in terms of negative entropy. Any cold object is simply more organised and less random than the same object once it is heated.

Schappeller had something to say about the Second Law of Thermodynamics. He said there was another and unknown thermodynamic cycle which runs opposite the Second Law. To name this idea we will call it "Reverse Thermodynamics". It is the reverse of the Second Law of Thermodynamics in that it leads to an increase in entropy. Not only is there an increase in order but there is an increase in cold! Schappeller, according to Mr. Watson's letter, built his spherical device primarily to demonstrate the principles behind this Reverse Thermodynamics. It was not designed as a practical machine.

To demonstrate the difference between the Second Law of Thermodynamics and Reverse Thermodynamics two theoretical machines shall be examined. Actually, a machine running according to the Second Law of Thermodynamics is not theoretical at all. Combustion machines are of this type. For simplicity sake we will use a wood burning stove such as the type invented by Benjamin Franklin for the heating of a house.

Wood is put in a hollow iron vessel with an adjustable hole at one end. The adjustable hole admits atmospheric oxygen. An initial small input of heat is added to the wood and oxygen until burning occurs. A great deal of heat is produced once the wood begins to burn. We know heat expands. Carbon, carbon dioxide and water vapour are also produced as by-products of the combustion. Entropy is increased. Since entropy is increased, so is pollution so perhaps we all can agree that this is a good example of the destructive technology so characteristic of the world in which we live.

In our example of a theoretical Reverse Thermodynamic machine the by-products of the previous example can be used as fuel. But Schappeller's machine has the additional property of being creative, that is, negatively entropic. Schappeller believed this creative process to be individualistic, so we need a specific template to use as a pattern for this creation. Heat, water, and carbon dioxide are fed into this machine. Quite amazingly, oxygen is yielded as a by-product of this reaction! The heat is also absorbed in Schappeller's Reverse Thermodynamic machine! This absorption of heat is another way of saying that the machine is implosive in nature rather than expansive or explosive as was the heat producing machine. What is most amazing, however, is that entropy is actually reduced yielding, something which has been created - wood!

Actually, this machine is not theoretical either. It exists and works as we speak. These machines are all around us. We call these machines "life". In this case our machine is a tree. In the tree, energy, sunlight, is absorbed and combined in a cold process with water and carbon dioxide to form wood. The template used as a pattern for this seemingly intelligent, creative, process is simply a seed. In this type of reaction the "cold" force is something other than the absence of heat. This cold is an active cold. It is a "densifying", implosive cold. It is a life-giving cold. This is a cold, life giving force. To quote Watson: "This process is life force and the reverse of the second law of thermodynamics; it is the vital force: Vril."

This is one huge difference between the physics of Schappeller and Schauburger and the physics of the Nineteenth Century. The physics of the Nineteenth Century explain everything in terms of the inanimate. Laws of physics are written using inanimate examples. Chemical reactions are described which stem from inanimate models. Animate models are simply made to conform with the inanimate assuming that life is just a special case which eventually will be shown to be nothing but chemistry and so subject to the same Second Thermodynamic Law as the inanimate. Schappeller and Schauburger both say in their own ways that this is not so. They say, each in their own ways, that a new and different law of thermodynamics applies to living forces. They say that this is more akin to a life process than previous theories allow. They say this force is creative. Those who subscribed to these new ideas claimed that it was not only a new physical law but a new science and that Germany would lead the way in this new science. Let us take a closer look at what is claimed to be the physics behind this new science.

The first concept to be considered is cold. Cold in this sense does not mean the mere absence of heat. This is interstellar cold, the cold found in the vacuum of space. In this relative vacuum, matter is not found in sufficient quantity to be used to measure this cold. Think about how we measure cold. We measure matter which is cold. We measure the heat in air or water for instance. In the absence of matter how would cold be measured? There is no doubt that if we could, for instance, place a thermometer in a glass of water in deep space, the temperature recorded would be at or very near absolute zero, 0° Kelvin or -273° Centigrade or -460° Fahrenheit.

The presence or absence of matter in deep space may be the subject of conjecture. The presence or absence of energy in deep space is something universally accepted. For instance, we all know that light passes through interstellar space. We see the proof when we look up at the stars, planets or the moon. Besides visible light, other electromagnetic radiations freely pass through space. These include x-ray, gamma and cosmic rays. Yet besides electromagnetic radiation many people now believe that in the depths of space there resides another form of energy with is found there as well as everywhere else all around us. This energy sometime goes by the name of "zero-point energy" but for our purposes we can simply call it "aether energy". It is sometimes argued that this energy is really the result of aether rather than the aether itself and that aether really is matter. For a moment, let us postpone this discussion and focus on the vast stretches of interstellar space which are filled with aether energy, near or at absolute zero.

Mr. Watson points out Dawson's words on page 83 of "The Physics Of The Primary State Of Matter" where he says: "Cold is not therefore the absence of heat, primary heat and cold having nothing to do with molecular action (in the cosmos) there are no molecules available".

The reader may recall that something strange happens to electrical energy at absolute zero. For instance, if a disc of conducting material is held at absolute zero and the disc is given an electric charge, the electric current will circulate around and around the disc forever, never losing its energy as it would if the disc were sitting on an office desk at room temperature. This property of cold is instrumental in the storage of at least one form of energy. The vast stretches of cold interstellar vacuum must be seen as a vast energy storage sea in a state of heightened negative entropy. Schappeller called this undirected matter-energy reserve potential "latent magnetism". Out of this latent magnetism, both energy and matter could be produced with the corresponding stimulation. The non-excited electromagnetic field was viewed by Schappeller as simply latent magnetism. Matter is a condensation out of bipolar aether. Therefore, electromagnetism is a product of matter and is nothing more than bipolar aether in a different condition. Latent magnetism could be, then, excited into matter. Latent magnetism could be influenced by either of the thermodynamic principles discussed, the Second Law of Thermodynamics or by Reverse Thermodynamics. This vast aether field, whose most notable characteristic is the property of cold, latent and awaiting stimulus, is the predecessor of both energy and matter as we know them.

Since primary cold, this vast reserve of negative entropy potential, is responsible for both matter and energy and since all energy eventually degenerates into heat, it follows that, as Davson puts it, again on page 83: "Primary heat, as may now be understood, is composed of cold energy". This seems like a surprising play on words, especially from a man of science, nevertheless, this statement follows perfectly from Schappeller's reasoning.

We turn now to Schappeller's concept of "stress". Both heat stress and cold stress can be applied to an electromagnetic field. Heat stress is the usual type of stress applied to electromagnetic fields in secondary physics. Secondary physics is the physics of our everyday world according to Schappeller. Primary physics is the physics dealing with the cold force and aether yielding matter and energy, which constitute the secondary reactions and so Schappeller uses the term "secondary physics" to describe our world as we know it.

An example of heat stressing of the electromagnetic field is the capacitor and the coil. A charged capacitor produces an electric field and a charged coil produces a magnetic field. A charged capacitor and coil, connected by a wire circuit alternately charge and discharge each other, producing electromagnetic radiation until the heat caused by the resistance of the wire degrades the whole process into heat. Heat stress on the electromagnetism is +/-.

Cold stress on the electromagnetic field is something totally new to our science and technology. It is also seen in terms of +/- but the machines used to produce it are not known in our world. Mr. Watson did not say this but if we return to our examples of heat stressed machines, the capacitor and the coil, the corresponding cold stressed machines might be the Schappeller sphere and the Schappeller coil electret. The sphere collects the charge through the magnets, holds and condenses it in its glowing centre corresponding to the

electric field of the capacitor. The internal coils filled with electret produce a magnetic field in the presence of the intense and pulsing electric field. According to my interpretation, the whole Schappeller sphere is a combined capacitor/coil combined into one machine made possible through an initial input of cold stress.

As in our example of the capacitor/coil interaction producing an electromagnetic wave, so an attraction exists between a machine obeying the Second Law of Thermodynamics and one obeying the law of Reverse Thermodynamics. This attraction can lead to interaction. For example, an imploding or centripetal vortex can couple with an exploding or centrifugal vortex. The centripetal vortex is an example of a system following the law of Reverse Thermodynamics while the centrifugal vortex represents system following the Second Law of Thermodynamics. We have all seen these two systems working together in everyday life. The common toilet is such a machine although the centrifugal side forms inside the drain pipe which is out of sight.

Perhaps there is another example which is more germane to our discussion. It is the diagram of the Vril power plant. (This engine diagram is used here as an example for discussion and is not a blind endorsement of the diagram's existence or accuracy.)

Internal plans for a "Vril-1" saucer, according to Polish historian Igor Witkowski.

In this interpretation of this diagram, we are really dealing with two separate devices. First, is the central spherical device which may be a refined version of the Schappeller sphere. An initial charge would be imputed into the sphere to start it after which the unit would continue to gather up the surrounding energy. This is a Reverse Thermodynamic machine. The sphere generates a magnetic field which could be offset by rotating the Schappeller device. The offset field would feed and so rotate the arms of the electric generator surrounding the sphere. The electric generator would gather electric energy, feeding the four large broadcasting fixtures on the walls of the saucer. These fixtures might be, for instance, Tesla pancake coils. The electric generator is an example of a machine complying with the Second Thermodynamic Law.

Both components of the power plant are bonded together in a single system since the output energy of the broadcasting fixtures on the walls of the saucer constitute additional input energy for the sphere. The two components attract one another and use and depend upon one another as they circulate and recirculate energy. As the energy level of one component increases so does the energy level of the other. Indeed, the biggest problem facing the use of such an engine may be getting some means of stopping it.

The actual levitation might be the particular electromagnetic radiation coming out of the sphere. In this interpretation, the broadcast fixtures are used to steer the saucer. Davson gives output frequencies for the sphere as 10^6 (20).

Mr. Watson points out in his letter that one reason machines utilising the Reverse Thermodynamic principle have not been recognised is that a cold stressed magnetic field is a cold machine. Even a centripetal vortex cools rather than heats. All our devices of measurement ultimately measure heat in some form. Measurement of cold is more difficult. The example already given, the problem of measuring temperature in interstellar space in the absence of matter is an example of this problem.

Finally, the reader will recall that Mr. Watson points out that electromagnetism itself manifests bipolarity, yielding four components in all. These are +/- hot electromagnetism and +/- cold electromagnetism. The reader will recall that two hot electromagnetic components can be joined (the capacitor and the coil) and set

into a cycle producing an electromagnetic wave. Is it possible that two complementary hot electromagnetic and cold electromagnetic machines could be set into cycle producing not a bi-polar but a quadropolar, 360° radiation to produce gravity, such as the one described by Dr. Richard Le Fores Clark?

Planned Uses for the Schappeller Device

If the above discussion has any meaning at all in the quest for an answer to the UFO question, one use for which the Schappeller device must have been destined was that of a power plant for a flying machine. Was this so? The Schappeller device had many planned uses. In 1930 this device was planned as a source of broadcast energy, reminiscent of Tesla, for both German homes and industry. The device could also be used as a generator, battery, transformer, or antenna (21). It is reported that toward the end of the war the SS researched the possibility of using this device in the form of a death ray (22). But additionally, and in answer to our question, the Schappeller device was envisioned as a levitation device for a flying machine. Here is some of that discussion from our sources:

"The new dynamic technology will, in the future, be able to drive electric locomotives and cars without the manufacture of costly armatures and everywhere through connection to the atmospheric voltage network. Hypothetically, is certainly the installation of a sufficient number of central amplification facilities which transports from the Ur-Machine the specific magnetic impulse from the dynamic spherical element. New types of aircraft with magneto-static power devices and steering, which are completely crash and collision proof, could be built for a fraction of the cost of today's aircraft and without the lengthy training of everyone who will be servicing these aircraft". (From "Vril Die Kosmische Urkraft Wiedergeburt von Atlantis" by Johannes Taeufer, page 48).

"Our goal must be to drive forward the space ship problem to new understanding and realisation! Here a definite postulate can be established: "A spherical space ship with its own atmosphere" also technical creation of small planets with world dynamic propulsion and buoyancy!. Will this be possible? -- Major powers in the world prepare themselves in any case presently, especially in Germany."

The above from "Weltdynamismus Streifzuege durch technisches Neuland an Hand von biologischen Symbolen" pages 11 and 12. Please note the use of the words "spherical space ship"(Kugelraumschiff).

From Davson's "The Physics Of The Primary State Of Matter", page 240: "The Rotor is laminated to prevent eddying and the magnets do not project; the Rotor periphery is thus entirely equi-radial. The Rotor is fixed to the shaft to be driven and the Stator is fixed about a metre above the earth's surface. The latter is, of course, flexible because the earth can include the sea or even the floor of an aether-ship."

From Davson, page 199: "As has already been explained, the new Technique will not concern itself with the air as a supporting medium, but directly with the aether. Therefore, the body may be a vertical sealed cylinder with conic ends or any other suitable form. Such a body is obviously rigid and inelastic, and it must contain an aether stress of sufficient intensity to support its mass against thither stress of the earth's stress field, which means that the glowing magnetism core in the Stator, provided in the body to be lifted, must be able to vary its intensity according to the height at which the aether-ship is to be raised and supported whilst in transit, as the aether stress or field, itself, varies inversely as the square of the distance from the earth's surface. The actual design and solution of all the various problems in the production of such ships, the choice of methods of propulsion, whatever independent or directional, belong to the new Technique, whereas here we are only interested in the principle as applied to the problem of Gravitation."

Finally, from Davson, page 177: "Now the reason that an unsupported body falls to the ground is primarily because it has "no hold" on the medium. It was previously explained that any inert mass or body has only a latent stress field which functions merely as the force of cohesion and has no mobility and thus only a latent internal stress field and no external stress field. This means that it has no "hold" on any elastic medium such as the aether or the air, therefore it must fall, and it falls towards the greater inductive energy."

If the inductive energy, through some exterior cause, could be made suddenly to increase enormously, there would come a point when the body would be supported, or rather suspended, before it reached the earth's surface. The new Technique could accomplish this by placing a Schappeller Stator in the body in question, where the body is suitably constructed, thus setting up a glowing magnetic stress field which would hold or keep the weight or mass of the unit body suspended, not in the air "the stress field would have no reaction on the air" but only on the earth's magnetic stress field. This is the basis of the new principle for 'aether ships'".

Employing the Schappeller mechanism is only half the total explanation. In a field propulsion saucer there are possible two types of "drive" needed. The first is the "Auftrieb" or levitation. Employment of levitation makes the craft buoyant. It weighs nothing. If it weighs nothing it can be moved very easily. "Antrieb", impulse or motive power is the second drive involved. It moves the craft directionally. Levitation only would be supplied by the Schappeller system. Directional movement is so far best explained, in my mind, using the Tesla pancake coils as explained by Bill Lyne.

Concluding Thoughts on the Schappeller Device

In the end, what can be said of the Schappeller device? Certainly, it did exist. It drew attention and funding from people within the German government of the time. It was studied by a qualified outsider, a British engineer, for a period of three years and was judged to be genuine.

However, there are some obvious problems. Exotic energies have been evoked which have not been explained satisfactorily. Therefore, the facts are not yet proven. Certainly more proof is required before the claims made for this device or the energies involved can be wholly accepted. For the time being we must put this discussion aside, awaiting further correlations.

There are some solutions connected with this device also. If we accept the idea that both the Schauburger and the Schappeller devices worked on the theory of implosion, then one explanation will serve to explain them both. It also allows for an aether-as-matter explanation. This may fit into the evidence gathered by Nikola Tesla. The commonality of these devices could then be sought and perhaps a more efficient device built as a result. We will pick up this theme again in the discussion section of this book.

It should be pointed out that the quest for this "new science" is not specific to Schappeller or Schauburger. Mr. Watson passed on these words from Ehrenfried Pfeiffer, a scientist who collaborated with Dr. Rudolf Steiner around 1920. Although he is not happy with the translation, he sent it as he found it which is as it is presented here:

"...the method of science, in a materialistic sense, is based on analysis splitting apart, disintegration, separation, dissecting and all the procedures which have to destroy and take apart, to work on the corpse rather than to grow, to develop, to synthesise. That the human mind was captured by these methods of braking apart: in that I saw the source of our present situation. My question (to Rudolf Steiner) was therefore: is it possible to find another force or energy in nature, which does not have in itself the objective of atomising and analysis but instead builds up, and synthesises? Would we discover that constructive force, which makes things alive and grow, develop adequate building up of methods investigation, eventually use this force for another type of technique, applied to drive machines, than because of the inner nature of this force or energy we might be able to create another technology, social structure, constructive thinking of man rather than destructive thinking? This force must have the impulse of life, of organisation within itself as the so-called physical energies have the splitting, separating trend within themselves."

My question to Rudolf Steiner in October 1920 and spring 1921 therefore was: "Does such a force or source of energy exist? Can it be demonstrated? Could an altruistic technology be build upon it?"

My questions were answered as follows: "Yes, such a force exists, but is not yet discovered. It is what is generally known the aether (not the physical aether) but the force which makes things grow, lives for instance in the seed as Samenkraft. Before you can work with this force you must demonstrate its presence. As we have reagents in chemistry, so you must find a reagent for the aetheric force. It is also called formative aetheric force because it is the force which relates the form, shape, pattern of a living thing - growth. You might try crystallisation processes to which organic substrata are added. It is possible then to develop machines, which react upon, and are driven by, this force. Rudolf Steiner then outlined the principles of the application of this force as source of a new energy..."

Since this quest for a new science with the accompanying new machines had a relatively long history in Germany, certainly pre- dating the 3rd Reich, it is almost certain that the Schappeller device or others built along a similar understanding were further developed during the Nazi period. What became of it after the war is not known. It can be assumed that this device did not escape the scrutiny of the numerous Allied intelligence units tasked with combing Germany for examples of German science. Perhaps someday a government report will be de-classified explaining all this as it was in the case of another free-energy machine, that being the Hans Coler device, which was declassified by the British in 1978 (23) and which worked, according to Mr. Watson, using the same principles of cold magnetism. Until that final reckoning comes, aspects of the Schappeller device will still remain a mystery. And until a more final reckoning comes,

the question of whether or not the Schappeller device was used as a source of field propulsion in German flying saucers, must be deferred.

Condensation-Induced Water-Hammer.

There is another little-known effect which has a high potential for being a useful technique, and this is the water hammer effect produced by the sudden condensation of steam. Under suitable conditions, the effect can be harnessed to provide motive power.

One of the techniques which has been used is shown above. Here, steam under 55 psi pressure is forced into a tubular structure through a ring orifice. That steam then passes through a doughnut-shaped nozzle where it hits a stream of heavily aerated water. The bubbles in the stream of water are drawn in by the venturi effect of the water flow past small apertures in the tube. The result is a rapid series of water hammer shock waves which, because of the shape of the shock wave chamber, boost the water as it exits from the tube. This produces a thrust in the opposite direction, effectively forming a jet engine which is particularly suited to water-borne vessels. In the diagram shown above, the device shown is designated as an Underwater Jet Engine. The diagram is from the web display at: http://www.newscientist.com/data/images/ns/cms/dn3321/dn3321-1_843.jpg and is copyright of the New Scientist.

William Hyde's 10 Kilowatt, COP=10, Electrostatic Power Generator.

This is best described by his patent, a slightly re-worded version being shown here:

This patent describes a device which can be a little difficult to visualise and so some colour shading of parts has been used to help matters. Essentially, it is two circular rotors spinning inside a section of plastic pipe. These rotors generate electrostatic energy which people have mistakenly been led to believe is not a source of significant power. This design by William Hyde has an electrical output which is some ten times greater than the mechanical input power required. A Coefficient Of Performance = 10 result like this, has to be significant, especially since the device is of fairly simple construction.

Electrostatic energy field power generating system

Patent US 4,897,592

30th January 1990

Inventor: William W. Hyde

Abstract:

Externally charged electrodes of an electrostatic generator induce charges of opposite polarity on segments of a pair of confronting stators by means of electric fields within which a pair of rotors are confined during rotation to vary the charge binding field linkages between confronting rotors and stators by a shielding action of the rotors in a plane perpendicular to the field flux. A high electric potential difference induced between the stators resulting from such rotation of the rotors, is transformed by an output circuit into a reduced DC voltage applied to a load with a correspondingly increase current conducted through it.

Description:

This invention relates to the generation of electrical power by conversion of energy from an electrostatic field. The conversion of energy from a static electric field into useful electrical energy by means of an electrostatic generator is already well known in the art as exemplified by the disclosures in U.S. Pat. Nos. 2,522,106, 3,013,201, 4,127,804, 4,151,409 and 4,595,852. Generally, the energy conversion process associated with such prior art electrostatic generators involves the input of mechanical energy to separate charges so that a considerable portion of the output is derived from the conversion of mechanical energy.

It is therefore an important object of the present invention to provide an electrostatic generator in which electrical power is derived from the energy of static electric fields with a minimised input of mechanical power.

Summary:

In accordance with the present invention, static electric fields are established between electrodes externally maintained at charge levels of opposite polarity and a pair of internal stator discs having segmental surfaces that are dielectrically spaced to confine thereon charges induced by the electric fields. A pair of rotor discs are rotated within continuous electric fields in planes perpendicular to the field flux to locationally vary the charge linkage established by the electric fields between the electrodes and stator discs. Such changes in charge linkage are effected by rotation of electrically conductive segments of the rotor angularly spaced from each other to partially shield the stator discs from the electric fields. The segments of each rotor disc have charged faces confronting the electrodes in its field to shield the stator disc over a total face area that is one-half the total area of the confronting segment surfaces on the stator disc to which the induced charges are confined. Charges on the rotors and stators are equalised by electrical interconnections established through the rotor shafts. The stator discs are electrically interconnected with an electrical load through an output circuit transforming a high potential between the stator discs into a reduced dc voltage to conduct a correspondingly multiplied current through the load.

Brief Description of the Drawings:

These and other objects and features of the present invention will become apparent from the following description taken in conjunction with the preferred embodiments thereof with reference to the accompanying drawings in which like parts or elements are denoted by the same reference numbers throughout all of the different views shown in the drawings and where:

FIG. 1

Fig.1 is a simplified electrical circuit diagram corresponding to the energy conversion system of the present invention.

FIG. 2

Fig.2 is a side section view of an electrostatic generator embodying the system of Fig.1 in accordance with one embodiment of the invention.

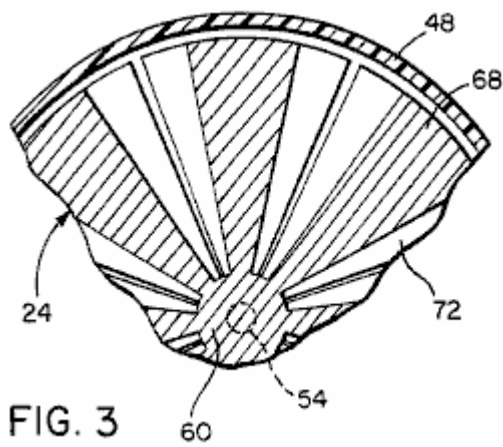

Fig.3 and **Fig.4** are partial section views taken substantially through planes indicated by section lines 3--3 and 4--4 in Fig.2.

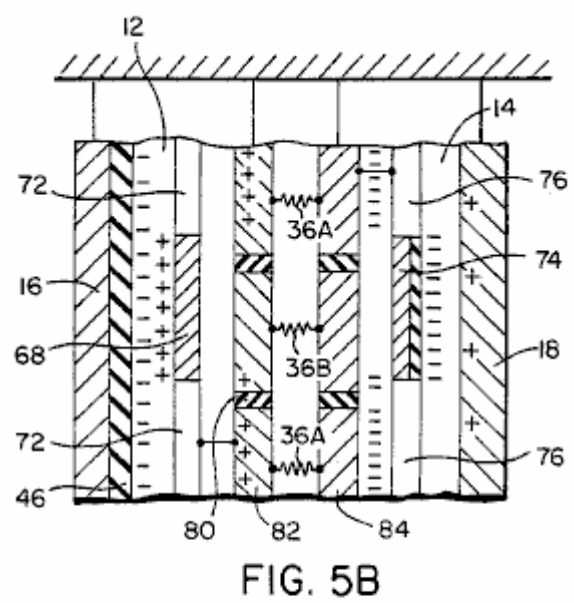

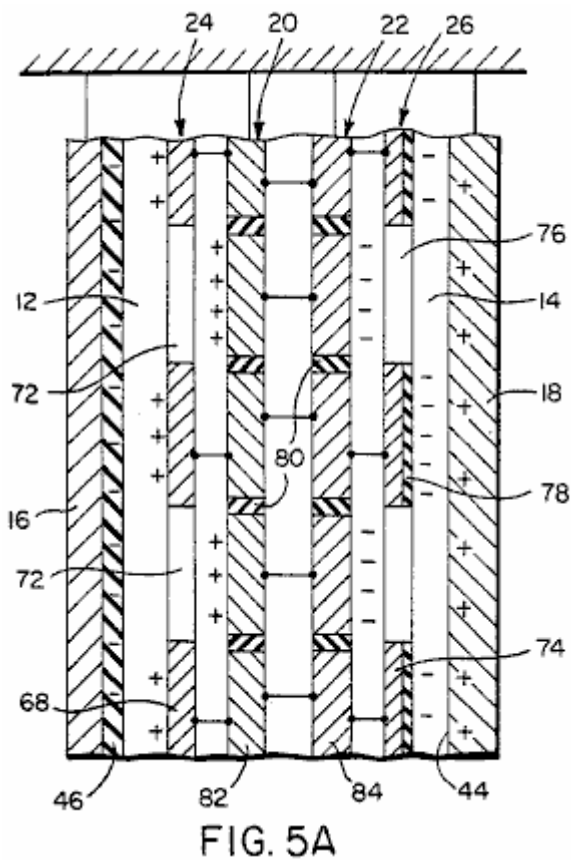

Fig.5A and **Fig.5B** are schematic partial laid out top views of the electrostatic generator of Figs.2-4, under static and dynamic charge distribution conditions, respectively.

FIG. 6

Fig.6 is an electrical circuit diagram of the output circuit of the generator shown in Fig.2, in accordance with one embodiment.

Detailed Description of the Preferred Embodiment:

FIG. 1

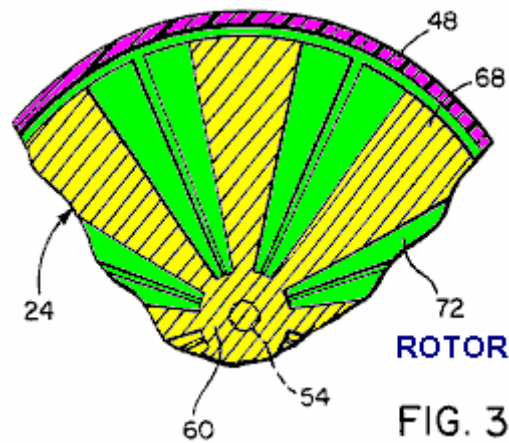

Referring now to the drawings in detail, **Fig.1** diagrammatically depicts the energy conversion system of the present invention generally referred to by reference numeral 10. As shown in **Fig.1**, the system includes a pair of electrostatic fields 12 and 14 established by electrostatic charges of opposite polarity applied to electrode plates 16 and 18 from some external energy source. Thus, the electrostatic field 12 is established between electrode 16 and a stator disc 20 while the electrostatic field 14 is established between electrode 18 and a stator disc 22. In accordance with the present invention, electrostatic charge linkages established by the flux of the fields between the electrodes and stators are periodically varied by displacement within the continuous energy fields 12 and 14 in response to rotation of rotors 24 and 26 aligned with planes perpendicular to their common rotational axis and the field flux, as will be described.

The rotors are mechanically interconnected with an electric motor **28**, as diagrammatically illustrated in **Fig.1**, which rotates them around their common axis. Electrical energy may be extracted from the electric fields **12** and **14** during rotation of the rotors **24** and **26** (by motor **28**) through an output circuit generally referred to by the reference number **30**. The output circuit **30** as shown in a simplified fashion in **Fig.1**, includes two pairs of current-conducting diodes **32A**, **32B** and **34A**, **34B**. The diodes of each pair are connected with opposite polarity and each pair is connected in parallel to one of the stators **20** and **22**. The diodes of each pair are also electrically connected across an electrical load represented by resistors **36A** and **36B** with capacitor networks **38A** and **38B** interconnected between each pair of diodes by means of which the voltage potential between the stators **20** and **22** is reduced in favour of an increased current through the electrical load.

Referring now to **Figs 2, 3** and **4** in particular, a physical embodiment of the energy conversion system shown in **Fig.1** is shown. The electrodes **16** and **18** are in the form of circular plates or discs made of an electrically conductive metal having external surfaces **40** and **42** adapted to be charged from the external source as already mentioned. The internal surface **44** of electrode **18** is thereby adapted to maintain a positive charge opposite in polarity to the negative charge of the electrode **16** which is maintained in a stable ion form within a dielectric surface portion **46** of the electrode **16**. The energy conversion system may be enclosed within an outer housing **48** to which the electrodes **16** and **18** are secured.

With continued reference to **Fig.2**, the stators **20** and **22** mounted by housing **48** in axially fixed spaced relation to the electrodes **16** and **18** are provided with bearings **50** and **52** supporting the powered rotor shaft driving the shaft assembly which has electrically conductive shaft sections **54** and **56** to which the rotors **24** and **26** are respectively connected. In the embodiment illustrated in **Fig.2**, the drive motor **28** is mechanically interconnected with the shaft sections **54** and **56** through an electrically nonconductive shaft section **58** of the power shaft assembly for the simultaneous rotation of both rotors **24** and **26** at the same speed and in the same direction about their common rotational axis perpendicular to the parallel spaced planes with which the electrode and stator discs are aligned. The electrically conductive shaft sections **54** and **56** are respectively keyed or secured in any suitable fashion to hub portions **60** and **62** of the rotors and are provided with flange portions **64** and **66** forming electrical wipers in contact with confronting surfaces of the stators **20** and **22**, which are inductively charged by the static electric fields **12** and **14** to equal levels of opposite polarity.

As more clearly seen in **Fig.2** and **Fig.3**, the rotor **24** has several angularly spaced, field linkage controlling segments **68** projecting radially outwards from the hub portion **60**. Each rotor segment **68** is made of an electrically conductive metal having a face **70** on one axial side confronting the adjacent electrode **16**. The faces **70** confronting the electrode **16** are charged positively by the electric field **12** extending between the dielectric surface portion **46** of electrode **16** and the stator disc **20**. While the electric field **12** projects through the spaces **72** between the rotor segments **68**, the rotor segments **68** themselves shield portions of the stator disc **20** from the electric field.

The rotor **26** is similarly formed with rotor segments **74** angularly spaced from each other by spaces **76** through which the electric field **14** extends between the positively charged surface **44** of electrode **18** and the stator **22**. The rotor segments **74** of rotor **26** as shown in **Fig.2**, are provided with dielectric surface portions **78** confronting the internally charged surface **44** of electrode **18**. While the rotor segments **74** are negatively charged by the electric field **14** within the surface portions **78**, they also shield portions of the stator disc **22** from the electric field as in the case of the rotor segments **68** already described. The internal dielectric surface portion **46** of electrode **16** and dielectric surface portions **78** of rotor **26** act as a stabiliser to prevent eddy currents and leakage of negative charge. Further, in view of the electrical connections established between the rotors and the stator discs, the charge on each stator is equalised with that of the charge on its associated rotor.

As shown in **Fig.2** and **Fig.4**, the stator disc **20** includes several segments **82** to which charges are confined, closely spaced from each other by dielectric spacers **80**. The segments **82** are electrically interconnected with the rotor segments **68** through rotor shaft section **54**. Similarly, the segments **84** of the stator **22** are electrically interconnected with the rotor segments **74** through rotor shaft section **56**. The stator segments **82** and **84** are therefore also made of electrically conductive metal. Each of the segments **82** of stator **20** is electrically interconnected through the output circuit **30** with each of the segments **84** of the stator. The stator discs being fixedly mounted within the housing **48**, centrally mount the bearings **50** and **52** through which the electrically nonconductive motor shaft section **58** is journaled as shown in the embodiment of the invention illustrated in **Fig.2**. Further, the total area of the charged segment surfaces on each of the stator discs is greater than the total area of the faces **70** or **78** on the segments of each associated rotor disc **24** or **26**. According to one embodiment, the total charged stator surface area is twice that of the rotor face area.

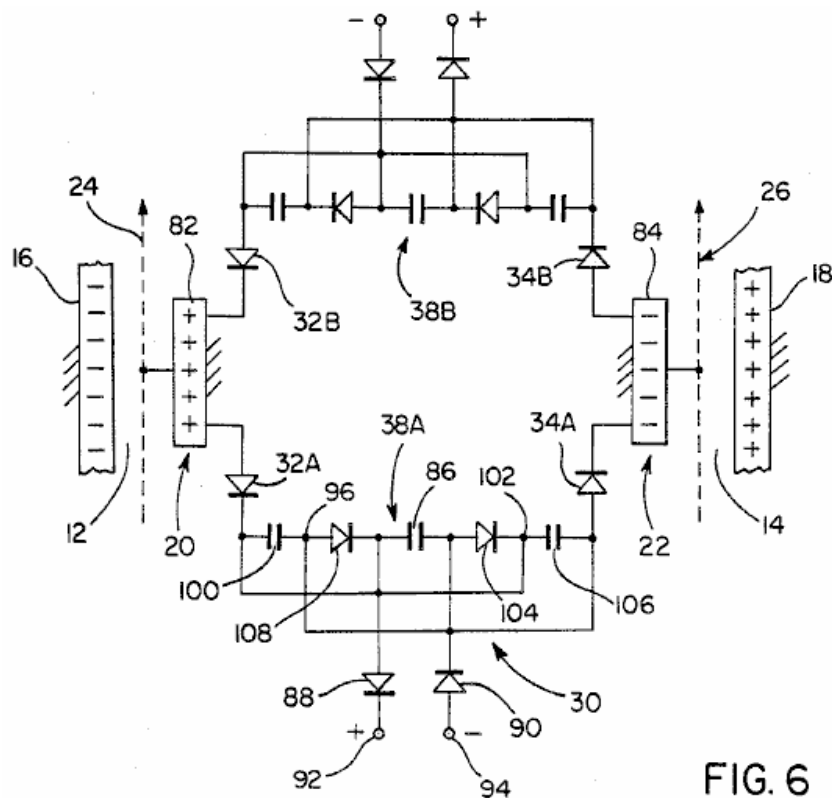

FIG. 6

According to the embodiment of the invention illustrated in **Fig.6**, the output circuit **30** includes the two oppositely poled capacitive circuit networks **38A** and **38B** connected across each aligned pair of stator segments **82** and **84** on the stators **20** and **22** by means of the oppositely poled diodes **32A** and **34A**. Each of these capacitive circuit networks includes a capacitor **86**, the opposite sides of which are connected by oppositely poled diodes **88** and **90** to positive and negative load terminals **92** and **94** across which a suitable electrical voltage is established for operating an electrical load. The diode **88** is connected to the junction **102** between diode **104** and one side of capacitor **106**. The diode **88** is also connected to the junction between one side of capacitor **100** and the diode **32A**. The diode **90**, on the other hand, is interconnected with the junction **96** between diode **108** and capacitor **100**. Also, diode **90** is connected to the junction between the other side of capacitor **106** and the diode **34A**. The foregoing circuit arrangement of capacitive network **38A** is the same as that of network **38B** by means of which aligned pairs of the stator segments **82** and **84** have the electrical potentials between them transformed into a lower voltage across the load terminals **92** and **94** to conduct a higher load current.

FIG. 5A

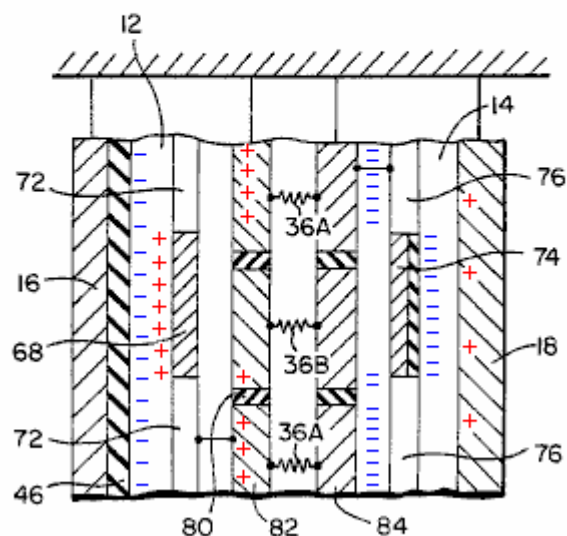

FIG. 5B

Fig.5A illustrates the distribution of charges established in the electric fields **12** and **14** between the electrodes and stators under static conditions in which each of the rotor segments **68** and **74** are positioned in alignment with one of the stator segments **82** and **84** to thereby shield alternate stator segments from the electric fields. The charges established by the electric fields are therefore confined to the faces of alternate stator segments confronting the electrodes and are equalised with the charges established on and confined to the shielding faces of the rotor segments confronting the electrodes by virtue of the electrical interconnection between the rotors and stators as already mentioned. As depicted in **Fig.5B**, when the rotors are rotated, the charge linkages established by the electric fields between the electrodes and alternate stator segments **82** or **84** are interrupted by the moving rotor segments **68** or **74** so that previously shielded stator segments become exposed to the fields to re-establish field energy linkages with the associated electrodes. Such action causes electrical potentials to be established between the stator segments **82** and **84**.

It will be apparent from the foregoing description that the electrostatic energy fields **12** and **14** of opposite polarity are established maintained between the externally charged electrodes **16** and **18** and the internally charged stators **20** and **22** under static conditions as depicted in **Fig.5A**. During rotation, the rotors **24** and **26** continuously positioned within the energy fields **12** and **14**, exert forces in directions perpendicular to the field flux representing the energy linkages between electrodes and stators to cause interruptions and reestablishment of energy linkages with portions of different stator segments as depicted in **Fig.5B**. Such energy linkage locational changes and the charge binding and unbinding actions between electrodes and stators creates an electrical potential and current to flow between stators through the output circuit **30**. Thus, the output circuit when loaded extracts energy from the electric fields **12** and **14** as a result of the field linkage charge binding and unbinding actions induced by rotation of the rotors. The stator segments **82** and **84** shielded from the electric fields by the moving rotor segments **68** and **74** as depicted in **Fig.5B**, have electric potentials of polarity opposite to those of the external electrodes **16** and **18** because of the field linkage charge unbinding action. Previously shielded stator segments being exposed to the electric fields by the moving rotor segments, have the same electric potential polarity as those of the external electrodes because of field linkage binding action. Since the forces exerted on the respective rotors by the electric fields **12** and **14** of opposite polarity act on the common rotor shaft assembly perpendicular to these fields, such forces cancel each other. The energy input to the system may therefore be substantially limited to mechanical bearing losses and windage during conversion of electrostatic field energy to electrical energy as well as electrical resistance losses and other electrical losses encountered in the output circuit **30**.

Based upon the foregoing operational characteristics, rotation of the rotors in accordance with the present

invention does not perform any substantial work against the external electric fields **12** and **14** since there is no net change in capacitance thereby enabling the system to convert energy with a reduced input of mechanical energy and high efficiency, as evidenced by minimal loss of charge on the electrodes. It was therefore found that working embodiments of the present invention require less than ten percent of the electrical output energy for the mechanical input. Further, according to one prototype model of the invention, a relatively high output voltage of 300,000 volts was obtained across the stators. By reason of such high voltage, an output circuit **30** having a voltage reducing and current multiplying attribute as already described, was selected so as to render the system suitable for many practical applications.

The Suppression of Knowledge.

Early in October 2011, Sir Christopher Woodhead, former Chief Inspector of Schools in England, stated that children should leave school at age 14 and become apprentices. While I personally have a high opinion of apprenticeships for certain professions, this appears to me to be a direct attempt to lower the education levels of the UK population even further than it already is now, where many sales staff are unable to perform even the most basic arithmetic as part of their jobs.

The basis for how we live our lives and understand the things around us, society, personal relationships, family values and the like, is rooted in what we are told by "the authorities". Unfortunately, much of what you have been told is just not true. You have been lied to about science, astronomy, the environment, global warming, government, taxation, war, energy, inventions, education, terrorism, health, finance and the media, to name just a few topics which spring to mind.

Science: There has been, and still is, systematic, deliberate, and frequently brutal suppression of scientific fact. We are being told that you have to "burn a fuel" in order to produce power which is then "consumed" when we use it to power our lives. This is a deliberate lie. We are told "scientific" things which are sheer fantasy and designed to keep the truth from us. The objective is to keep the people of this planet ignorant, weak, and subject to the people who know the real facts, and to remove all possible wealth from the ordinary person.

Astronomy: We are told that the only way we can get into space is to use rockets. The people who say this not only know it is a lie, but they themselves have had electrogravitic drive vehicles for at least fifty years now. This sort of rubbish is roughly the equivalent of telling people that they can only get around by hopping on one foot. We are told that the speed of light is a constant and that is a lie. We are told that nothing can go faster than the speed of light, and that is a lie. We are told that gravity depends on mass, and that is a lie. We are told that the Earth is the only planet in our solar system which has an atmosphere, and that is a lie. In fact, almost all of what we are told is incorrect.

The Environment: We are told that we need to run our lives by burning "fossil fuels" which are limited in quantity and so there is "an energy crisis". While some oil is produced by the decay of organisms and vegetation laid down in earlier eras, oil wells which were pumped supposedly dry are actually filling up again with oil created in the crust of the Earth and which does not come from decaying vegetation and organisms. Nor is there the slightest need to burn oil for power, or have central power stations and fragile wires running all over the countryside. Those things are wanted by the powerful elite in order to control ordinary people and to part them from their money.

Global Warming: We are told that man's burning of fossil fuels is causing global warming through the production of Carbon Dioxide. This is the most ridiculous rubbish possible. Carbon dioxide is a natural gas, essential for plant growth, which in turn is essential for our survival. Carbon dioxide levels have long since reached the level where any increase has almost no further effect on warming. The percentage produced by man is trivial, as the vast majority comes out of volcanoes, the next largest amount is produced by animals and insects, and man's contribution is minor. Global warming and global cooling are natural events which were taking place long before man was around in any significant numbers and certainly, centuries before the burning of fossil fuels started. The contribution from all of the cars in all of the world is only about 1.7% of man's minor contribution and the fussing about "carbon footprint" is only a con which is being used to extract more money from the ordinary person.

David Archibald in this document http://www.davidarchibald.info/papers/Climate_Outlook_to_2030.pdf, published the graph shown here in 2006:

This graph clearly shows that even a big increase in the present carbon dioxide level has almost no impact on atmospheric temperature. It has also been calculated that an increase to 620 ppm would give a temperature increase of only 0.16°C. The graph shown above, together with its calculations should have ended any further discussion about reducing carbon dioxide emissions. However, this has most definitely not been the case.

For financial reasons, a decision has apparently been taken to keep up the pressure on carbon dioxide reductions, resulting in senseless investments on new technology for capture and storing carbon dioxide, “beautiful” windmills absolutely everywhere and the mandatory use of bio fuel (which has a negative impact on food production). Don’t forget about all the revenue which ‘governments’ are getting from “climate taxes”.

All these taxes and the massive spending of taxpayers money, really threatens the economic foundations of the whole of the western world, but worse still are the consequences of the commitment to bio fuel. This mad strategy has caused a near doubling of the cost of cooking oil and essential foods such as rice, because farmland is now being used for the production of bio fuel. These increases are hitting poor countries the worst as the people can no longer afford to pay for basic necessities.

If the intention of the IPPC and the world’s politicians is to starve people to death, then they are definitely on the right track through their continued insistence on the supposedly harmful effects of carbon dioxide. In reality, the greenhouse gas which has the most effect is actually water vapour which accounts for about 98% of all warming. I wonder how the politicians are going to prevent water vapour from getting into our atmosphere !

In his video “An Inconvenient Truth” Al Gore points out the close correlation between the fluctuations of global temperatures and the levels of carbon dioxide in the atmosphere. He point out strong rises and falls in the average global temperature (nearly all of which are before mankind started burning oil) and the related strong rises and falls of carbon dioxide concentration in the air. What he is very careful to avoid mentioning is that the changes in carbon dioxide concentration, lag behind the global temperature changes by some 600 years. The carbon dioxide concentrations are a **result of** the global warming and **not** the cause of it.

Government and Taxation: It appears that the sole purpose of government is to enrich the people in power at the expense of the ordinary person. People in a democracy are supposed to be “free” but this is a gross illusion. If you were working all week in a company and at the end of the week you were paid £1,000 cash. When you start going home, an armed gang of thugs threatens you and steals £800 of your £1,000 and that happens every week without fail. So, what do you think of that arrangement? Good or bad? That is what government does for you at this time. But, you say, “we live in a democracy, so we can fire the politicians”. That is the equivalent of having three exits from your workplace and each exit has a different gang of thugs ready to rob you. Yes, indeed, you have choice. You can choose which exit to use and therefore, which particular gang of thugs robs you.

You think that is overstating the case? I have seen it calculated that 80% of everything you earn is taken away from you in “taxes” and there is justification for that figure when you consider what contributes to the cost of everything you do. You pay taxes. Can you remember being asked if you would be willing to pay tax?

Oh, but you say, we need taxes in order to pay for public services, health, education, transport, etc. Yes we do, but how much of your money actually goes on that. In the UK there is a large annual “car tax” which was introduced with the excuse that it was needed to finance the building and repair of roads. I understand that at least 85% of that money is not spent on the roads. There is a massive tax on vehicle fuel and I have seen the figure of 85% mentioned. If that is the case, fuel should only be one sixth of the price charged and that extra cost finds it's way into almost everything else, food, clothes, electrical goods, all manufactured items, heating, electricity supply, gas supply, etc. etc. In addition, there are major taxes on alcohol, tobacco, service industries, travel, and everything else that ‘politicians’ can think up. So you're a free person living in a free democracy? Who are you kidding? Do you actually have “sucker” stamped on your forehead? For further information, visit <http://www.yourstrawman.com> where the facts are laid out clearly.

Take the case of America. The objective of the Civil War was to make money for the unscrupulous. A really major fraud was perpetrated on the American people at that time. They believed (and most still do) that the United States is the government of the American nation. That is not the case. “The United States of America” is actually a commercial conglomerate of private corporations, corporations with names like “The State of Arizona”, or, “The State of Texas”. Federal taxes are imposed on the American people, but that goes directly into the private finances of these companies and not a single dollar of it goes to benefit any ordinary American citizen. There is much more detail on this in Chapter 15.

War: The general public is held subject to what passes for ‘government’ through fear and ignorance. The government announces that some country needs to be attacked and invaded in order to “free” the people and establish democracy. So, generally without any realistic reason, that country is attacked and invaded, much of the civilian population killed, massive property damage inflicted, and great distress and hardship caused for many people. This is organised by the politicians. Do they themselves take part in the fighting? No. Who benefits from the war? Answer: the arms manufacturers, and companies such as Halliburton which are paid taxation money to rebuild what the local army has just spent time destroying. The country attacked is likely to have it's assets stolen and then be saddled with a massive fake debt so that it can be forced to pay incredible amounts of “interest” for decades afterwards. The lucky country has been attacked, damaged, citizens killed, infrastructure destroyed, assets stolen and then robbed for years afterwards by the people who caused that devastation. You did say that you live in “a free democracy”, didn't you?

Energy: The energy companies are very keen to sell you fuel for you to burn to “get” energy to run your vehicles, home appliances, heating, etc. They are also very keen that you should not discover that you are surrounded by energy which can be used for all those things without paying the local energy company anything. Most people imagine that the electrical power which flows out of the wall socket in your home (and for which you have to pay a good deal), comes along the wires from the generator station which burns fossil fuel to drive the generators. That is not the case, as not a single electron of the current you use actually comes from the power station but instead is collected locally from free environmental energy. If you knew how to do it, then you would have no need for the power company, power lines across the country, power stations or oil drilling and shipment around the world. Cars don't need fuel to run but that information is heavily suppressed and you are lied to when you are told that you need to burn a fuel to power your life.

Inventions: When they discover that there is such a thing as free-energy, most people think that what is needed is a scientific breakthrough in order to develop the technology needed to let everyone have free energy. The reality is quite the reverse as the technology has been discovered and implemented literally thousands of times. You are being lied to when you are told that free-energy is “impossible”. I am reliably informed that in America alone, more than 40,000 free-energy patents have been confiscated by the (private company called the) Patent Office. Inventors are then silenced by a gag order under the absurd excuse that the invention is “of National Security importance”. Inventors who don't try to patent their inventions are intimidated, some are murdered, some are attacked and their reputation smeared, some are illegally put in mental institutions, some are framed and all suffer massive financial opposition if they try to start manufacturing a product for sale – not even Cal-Tech managed to get past that financial block. I personally know several researchers who have been unlawfully intimidated.

Education: There is a massive program of “dumbing-down” education combined with the deliberate teaching of things which are known to be completely wrong. After only a few decades of this, many adults can't perform basic arithmetic or construct simple sentences in their native tongue. Science and Engineering are neglected and most people don't understand how things work. Most schools no longer allow

schoolchildren to perform experiments in chemistry or physics, usually with the excuse that it is 'too dangerous'. University students are told that there is no such thing as perpetual motion, which is as laughable as saying that water isn't wet. Newton actually said that gravity is a push and not a pulling force as indicated by the mis-translation of his Latin original text. This incorrect notion of gravity is still taught in spite of the fact that many governments have had electrogravitic drive vehicles since the early 1960s, driven by electromagnetic waves just below the frequency of infrared, disproving what is supposed to be Newton's theory, in a most resounding fashion. Any academic who steps out of line and admits that students are being taught rubbish, is immediately attacked with every possible means to discredit, ridicule and isolate him. The objective in all of this is to manoeuvre the general public into a weak position where they are ignorant, uneducated, fed false information and distracted with things of no importance. The ultimate aim is the slavery of the masses without them even realising that they are being enslaved.

Terrorism: The main way to make people give up their rights and do whatever you want is through fear. The book "1984" (dated that way because it was written in 1948) explains how this is done. Fictitious enemies are invented in order to frighten people and stop them complaining when vast amounts of their money is given to vested interests under the guise of being steps to protect them from this imagined danger. The "cold war" was completely fake with both sides using it as an excuse. The invasion of smaller countries is never, ever, for the reason given publicly, but is always for financial gain by the people in power and their commercial colleagues. The reasons given for these invasions are so ridiculous that it never ceases to amaze me that the public actually accept and believe these wild stories. One of the strands of this continuous deception waged against the public is fake "terrorism", frequently bolstered up by "false flag" attacks to discredit the perfectly innocent people who are supposed to have made those attacks. Any real terrorist attacks are normally a response to atrocities committed against the supposed "terrorists". The commercial companies which pass for governments, are the biggest terrorists around.

Health: The pharmaceuticals industry is one of the biggest money-making operations on the planet. It may come as a shock to you, but they don't want to cure people. Instead, they want people to go on buying expensive medication at heavily inflated prices. Long term health treatments are their ideal situation as that provides them with a continuous revenue stream. Several people have come up with very effective cures for cancer and other serious illnesses, and those people have received the same unjustifiable, outrageous treatment as do the inventors of free-energy devices. The pharmaceuticals industry is well aware of the highly beneficial effects of colloidal silver, but they will never produce any as they can't patent it and charge highly inflated prices for it. Consequently, they are not interested as their only objective is to make money, and it is definitely not to cure people.

Bob Beck's Electronic Pulsar.

The late Bob Beck emphasised this in his video lecture which may still be available at:

http://video.google.com/videoplay?docid=-3383948315844437935&ei=XdqBSruck5_sqAPr28irBg&q=Suppressed+Medical+Discovery%3A+Dr.+Robert+C.+Beck+%28+Cancer%2CAIDS%2C+anything+viral%29#

Here is an excerpt from that lecture:

For the last five years I have spent my own money (no government or university funding) in investigating a thing which has proven to be the most remarkable thing for all diseases that I have ever heard of personally, and I have been in this field for about forty years.

I have a stack of IRB Studies – PCR laboratory reports from major hospitals around the United States, and until these are peer-reviewed published, I am not supposed to show them to anyone who is not a medical doctor because of patient confidentiality.

Now, how many of you have read that there is no cure for AIDS? That is an absolute lie. There has been a perfectly workable, 95% accurate cure for HIV and cancer and herpes and hepatitis and Epstein-Barr and about a dozen other incurable diseases, which was invented on March 11th 1990 at the Albert Einstein College of Medicine in New York City by Drs Kelly and Wymans.

And what happened to this breakthrough which is far more important than penicillin, antibiotics, anything you can name? - it has been suppressed. And why has this information been withheld from you – information which you can easily prove for yourself (don't take my word here for anything: check it out)? I found recently that the Mafia owns about 51% of major pharmaceutical houses as well as working the other side of the track with the *illegal* drugs from South and Central America and China.

The medical cartels in this country (USA) will charge you from \$50,000 to \$200,000 if you have terminal

cancer and this is for surgery and chemotherapy and radiation and hospital care.

Consider a packet of Wrigley's Spearmint chewing gum. That packet of chewing gum cost me a nickel (5 cents or \$0.05) when I was a young man and I paid \$1.32 for that packet at the Chicago Airport recently - \$1.00 for the gum plus \$0.32 for taxes and handling. The price of that package of chewing gum is every penny (cent) that it takes to cure [and I'm not supposed to use this word as only a doctor may use the word 'cure'] most of the known diseases in America today. And why haven't you heard about this? – because General Electric, Westinghouse, and the other companies have billions of dollars tied up in X-rays, CAT scanners and MRIs which are leased to health organisations, and for \$1.32 you can cure yourself without doctors, without pharmaceuticals, without medicines, certainly without surgery, certainly without chemotherapy, without any drugs, without any herbs, any homeopathy remedies – you can do it for yourself and it has been done.

People keep asking “why haven't I heard about this, why are there no hospital studies?”. There are hundreds of them. Here is one test result: At this date, the eleventh of August 1998 this patient had only about 3,063 particles of HIV in his blood. But now, as this test develops, the PCR on the third of November 1998, (several months later), the count was less than 1 in a hundred, which means that the test result was zero as far as this test was concerned. We have a stack of these reports a foot and a half (45 cm) deep, where **every one** of these full-blown AIDS patients, every one even though some of them were on life-support systems or needed attendants to lift them from the bed, these people are symptom-free now. Every single one of them is back at work. Not one of them has the symptoms of AIDS. So, if you read in your newspaper ‘the proceeds of the baseball game this Saturday will be donated to a search for a cure for AIDS’ that is an absolute lie.

There is, and has been, a cure for AIDS – **all** AIDS – a cure for about 95% of cancer, a 100% cure for Epstein-Barr, hepatitis, lupus, about a 50% cure for herpes, and I've been funding these out of my own pocket. I have absolutely nothing whatsoever for sale. God has been exceedingly good to me – I think that I am going about my Father's business here, and I am paying for it myself and I am giving to the world.

There is a free paper available entitled “Take Back Your Power” (a web download link for this is <http://www.free-energy-info.tuks.nl/Beck.pdf>) you do not need doctors, nurses, chiropractors, herbs, pharmaceuticals, surgery. Only if you are going along with the politically-correct solutions do you need these things that your neighbours have been depending on for all these many generations. There was paper entitled “Blood Electrification and Immune System Restoration with Microcurrents – A Proven, Startling, Rapid, Inexpensive and Safe Discovery for Positive, Controllable Remissions”. Now we found that this information has been suppressed. The doctors who discovered this, and let me tell you about the discovery: In 1990, they put a couple of small platinum wires into a Petrie dish that contained highly infected human blood, and the infection there was a very, very strong dose of HIV which was supposedly the cause of AIDS. They found that when they had electrified this blood, the HIV could no longer attach to any receptor sites in the blood. That means that the healthy cells could not be infected by the HIV. The only mention of this incredible discovery was in *Science News* March 30th 1991, page 207, ‘*Shocking Treatment Proposed for AIDS*’ and it tells about how these two doctors had given a paper on this process saying, ‘the experiments described on March 14th at Washington DC at the first International Symposium on Combination Therapies, showed that the shocked viruses lost the ability to make an enzyme crucial for their reproduction and could no longer cause the white cells to clump together – the true key signs of viral infection.

The only papers which I was able to find that got into the American press were *Science News* and article in *Longevity News* ‘*Electrocuting the AIDS Virus*’. But what happened in the *Longevity* article (which was December 1992, page 14), was that Dr Colley said ‘it will be 15 years before this process is ready for human experimentation’.

We have been doing it, sub-rosa, with patient consent, for over five years here, and we have the test results to prove it. When I was lecturing to a room of about 800 people, an 80-year old man came up and said ‘**Bob, I was sent home today, my cancer had metastasised all through my system. I was told to go home and make my will, as I had at the most, about two or three weeks to live. I went home and I made my will and I saw your article in some magazine and I did it. I am now free of all cancer. My biopsies are clean, my CAT scans are clean. I went back to work, and being an attorney, I had to work sixteen hours per day to catch up on all the work I had missed while I was in intensive care. Now I'm jogging three miles per day**’ (and there were tears running down his face).

We have had women who have had lupus for about ten years, barely able to make it from the couch in front of the television to the bedroom. They are back at the malls now, spending their money, walking around and able to hold jobs full-time. Do any of you know Linda Wright ? She brought in a clean blood test one day

and said 'my doctor had to send this to two different labs – he's never seen a person with clean blood after that person has had lupus'.

We have dozens of these people, and not one of these people went to the doctor for the cure, except for the people who are on this Institutional Review Board study at a hospital in Huntington Beach and Newport Beach, California. Now, the point is, in my humble opinion, and we can put anything against this because we know that it is true at this time, when I first started this I thought 'this is kind of interesting'. I have looked into five hundred things that never worked, the Rife Machine never worked, Holderclarke's Machine does not work, many, many, many of these devices work only marginally, and I felt 'I'm about to be taken in again', I have built Mucalsky multiple-wave oscillators as you know. I have built almost every electro-medical device since I've been in California (since World War Two began), and these things worked at best, marginally. But the thing which you can build for yourself, there is nothing that you have to buy. The circuit diagram and all of the instructions for building this, are in the paper. This is the one which I designed in 1991 to make an experimental study with, and you can get a kit from an electronics store. I get not one nickel from the tens of thousands of dollars worth of these kits which they have sold.

There is a parts list on page 4 that tells you what is needed. Even if you don't know what a resistor is, or a capacitor is, put the list on the counter at Radio Shack and tell them to give you what is on the list. The retail price ready-made is around \$150. If you build it yourself it will cost \$15 to \$20 and this machine will not only make colloids, which is the most powerful medicine known to man, (which is why the FDA has stamped it out recently).

SOTA Instruments Inc. Canada (1-800-224-0242) builds these devices because the owner read the article in PACE magazine and his wife had chronic fatigue syndrome and Epstein-Barr so badly that she was non-functional. She is now up and around and is totally well today because my husband built this little box for about \$15. The box straps on the arm with the electrodes positioned on the radial and ulna arteries and puts a very small electrification into the body which removes **all** parasites, viruses, fungus, microbes, pathogens – everything in the blood which does not belong there and was not there the day that you were born, eventually (after two or three weeks) being neutralised and discarded by your body, dead or alive by the spleen, the kidneys and the liver. This is darned exciting but when the hospitals tried to patent this, US Patent 5,188,738 presented to Dr Colley on February 23rd 1993, describes the process, as do fourteen other patents from Harvard MIT, page 1 column 1 says ‘because of this problem (the fact that there is no known antibiotic or vaccine for any of these incurable diseases) the present invention has been devised to attenuate any bacteria, virus (including the AIDS HIV virus), parasites and fungus contained in blood contributed by a donor, these being rendered ineffective for infecting a normally healthy human cell’. Before these claims were accepted by the patent examiners, they had to provide the examiners with massive proof.

Now there has been a cure, a known cure and it costs \$1.32 per patient so there is no money in this if they are trying to sell you combination therapies for \$20,000 to \$60,000 per year.

I strongly recommend that you get the paper as it contains the exact electrode locations which have been found to work the best and get the maximum current into the blood. It is almost as if God the Creator had locked the back door approach to the problems and with an adversary like the Holy Spirit which is within – the Bible says ‘look within, not without’. And this time, the adversary is within. The ‘aliens’ in your blood are the things which are holding down your lifespan to seventy or eighty years. Many, many generations ago, according to the sacred texts, they lived to be several hundred years old, Solomon, David, Methuselah, etc.

So, we have raided about a dozen different medical textbooks including Grey’s *Anatomy*, and we’ve published the exact spots where you can access the lymph tissue where these germs are going to be hibernating. After you clear yourself and get a clean bill of health, after three to five years you will re-infect yourself when many of these viruses which are latent, start germinating. And with this information, and these circuit diagrams and these instructions, we have literally given you back to yourself.

We are going to show you all of this before I leave here. This is not my opinion any more, we have enough proof that it is a statement of fact and we can bank on it. If you are too lazy, too stupid, too electronically impaired or too frightened to build your own, there are forty known companies (and probably a hundred that I know nothing about) that are building these things full-time and they are getting the most remarkable reports back. I do meet these people, and NO, I do not get a nickel from any single one of these companies, and all of this information is in your paper.

Now what else do we have to watch for here. Nobody has ever to this day died of AIDS. Did you know that? They have died of the opportunistic infections, pneumonia, Carkinson’s sarcoma, etc. etc. that can attack and ruin your body when your immune system cannot handle the load, in fact it is called ‘**HIV**’ (**H**uman **I**mmune-deficiency **V**irus) ‘**AIDS**’ is **A**cquired **I**mmune **D**eficiency **S**yndrome. Now this is the only way that I know of, I know the people who have written the books on ozone therapy, I won’t mention their names, I know the doctors who are using all of the herbs and drugs. I have talked to the people who worked with Dr David Ho who was on last week’s *Time* magazine cover as the Scientist of the Year, who has discovered that if you use two or three chemotherapy agents at the same time, you have a cocktail effect and it reduces the HIV count, the PCR count in the blood tediously. But what he didn’t tell you, and I think I’ll read this which was in *The Los Angeles Times* December 10th 1996: “Drug combo knocks HIV down, not out”. And a basic thing happened, they took some of these patients who were on combination therapy, which incidentally cost \$20,000 to \$60,000 per year, as soon as they stopped taking these cocktails, they got immensely elevated counts up in the millions or billions of AIDS counts, as though these chemotherapy agents, (AZT, DDI, DD5, etc.) had held this viral load down in the blood as long as they were taking it. The minute they stopped, it rebounded and many of the people were critically ill and they had to put them back on it immediately.

So, once you start on this cocktail therapy, you are stuck with it for life, as long as you live, and as you know from the International AIDS Conference in Japan last year, they found that none of these AZTs etc. prolonged the life of one single AIDS patient by even one day. Their’s is simply a promise, they are engineered to get your money while they give you hope. I was beaten up and bloodied; I was hit over the head and had blood running down my face, by ‘AIDS Act Up’ David Buller it was that was running this crusade in New York city in February. He called the New Yorker Hotel and said that they would burn down the hotel, so they gave me a bodyguard (who wasn’t around there all the time) and said ‘Bob, do not use the

front door but go around the back and use the service entrance – never go out the front door of this hotel. The last day when I was there and I had to run out to get a shuttle to take me to the New Jersey airport to bring me home, there was a guy standing across the street with a video camera and a guy who hit me over the head and bloodied me, and I didn't chase him down the street because my knees aren't very good as I don't have any cartilage in them.

But when's the last time that you saw me Ivan – about three years, four years ago? Do you notice anything that's different? I lost 130 pounds – I weighed 290 and I have pictures of me to prove it. My hair on top was thinner than some of my old good buddies here. As soon as I got rid of the adversaries – the aliens in my blood, my immune system took over and I got rid of the half a pound or so of parasites which every man, woman and child in America (if he's more than four days old) is carrying. A new-born baby, after four hours has breathed enough air to become infected. If you live in America, there are 140 **known** indigenous parasites. If you live in Africa or the tropics, there are 500 identified and known parasites and probably half as many again that are unknown. When we got these parasites out of my body by wearing this device on my wrist, an amazing thing happened. I began losing weight like crazy. I thought 'my God, have I got stomach cancer or am I wasting away with something?'. No, I was in better shape than I was before I started.

This is a theory: about 30% of the parasites which live in human beings, and these can range from fourteen feet (4.27 m) long if they are a tape-worm down to microscopic size (which is why they have to use microscopes to do the stool analysis if you go in for a check), these parasites were setting my appetite. If you will think about this for a minute, it is not what you eat or how much you eat that has anything whatsoever to do with your weight. It is how much of what you eat you store as fat because the parasites have changed the P51, the leptin and about five or six known neuro-transmitters in the hypothalamus to feed them tomorrow. Many of these parasites have co-existed with mammals – apes, elephants for twenty million years and the anthropologists will tell you that they find them whenever they find a carcass frozen in the ice floes, these things have had parasites for as long as ever man has been on the planet. These parasites have learned to use you as a meal and not kill you because then they are going to die themselves, like ebola which runs its course in a couple of weeks. Many of these viruses do that, but these parasites almost kill you and use you for a meal in the same way that we send cattle to a feed loft before we take them to market. And when these parasites vanished from my body, and this is provable by dark-field microscopy, phase-contrast microscopy, any doctor who does this analysis can prove it, you don't have to take my word for it, I lost all of that weight and before this time I had offered \$10,000 cash currency 'under the table' to anyone who could get this weight off of me.

I had tried dozens of diet plans. I had tried these canned-meal Jenny Craig type adventures. I had been injected with pregnant mare's urine. I know that some of you have been through the same things. I had taken legal amphetamines to control my appetite ... I had tried everything until I had nearly killed myself. And until I found the true cause of what I believe is about 30% of the people who are overweight, and this was certainly me, I was terribly embarrassed to find the airline stewardess running down the aisle with a seat-belt extender because the seat-belt wouldn't fit around me. I couldn't sit in the booth in a restaurant because I'd have to sit on a chair, etc. etc.

The lady at the back of the room, Jane had inoperable cancer when I met her. She said "I'm going along with blood-cleansing here, and not the chemotherapy and radiation which the doctor had said that if I do not have I will surely die". And her daughter Cathy was outraged because her mother didn't do all of this chemotherapy and have her hair drop out ... Now she is totally well. Her last several physicals – biopsies and CAT scans – have shown not one speck of cancer anywhere in her body. Neither have dozens and dozens of 'terminal' cancer patients.

Now, why does this work for cancer? We started out working with viral and microbe and parasitic diseases. When oncologists in the East began reporting many, many, many cancer cures, we had to have a telephone conference between about four or five of us. Now what's really happening here? I don't believe it until I see the medical proof. So I guess you know that about three months ago *Explorer* magazine published an article entitled '*Total Cancer Remissions through Blood Electrification combined with Silver Colloid*'. And this article of two pages is reprinted in its entirety in the paper which you should be taking home with you.

Social Security does not want you to live if you get to be 65. I'm now way past that. I don't act like it, but I am way past that, I'm in my seventies. The Director of Social Security – I will not mention his name because he picks me up at the airport when I'm in Washington and drives me where I'm going – I've stayed in his house – says 'Bob, we want anyone who reaches 65 to be stored like cord-wood in an old-age home and given mind-control drugs like valium and let him die because Social Security is bankrupt **now**, it won't be *bankrupt in five years time* as it is bankrupt now. And if you restore perfect health to these people with a device that will fit in your shirt pocket, the job market will not absorb the people getting out of college today.

Even if McDonalds has a smart cash register, they can't add or subtract, they can hardly write a paragraph and you want to get these experienced people back in the jobs market?'. I said 'hell yes!' I was 65 nearly ten years ago.

Another problem: this steps on the toes of all the vested interests. They are expecting to make hundreds of thousands of dollars off of you: Health Management organisations, insurance companies, hospitals, ... If you own a boat that thing is written into the budget of the boat builder down there in San Pedro. These medical people expect to see you come in there some day and spend a lot of money, but if you do this for yourself, you will get well. There are seventeen of us who I know of, and I know sixteen of them personally, who this day have immortal blood. Now this is a rather dramatic claim, so let me tell you what it means. Toward the end of last year, there was a dark-field microscopist 'Mike', you know his name, he is world famous, he's the fellow who trains doctors all over the world how to use this type of technology for diagnostic work. He invited a chap in who had been on one of these devices for about six months, and he said 'Let's look at your blood', so he pricked his finger, put that drop of blood in a microscope slide and looked at it. And he said 'you don't have any background clutter in your blood'. Of course, they couldn't see viruses as this was a light microscope with a magnification of about three thousand times, back-illuminated. He said 'just a minute – I must have done something wrong', so he stuck another finger, then he went to the earlobe and made a slide and said 'what have you been doing? anyone who has ever come to me, man, woman or child, in the last thirteen years, you can see the parasites, many of the germs, microbes and bacteria swimming around in the blood but you don't have any at all. The patient said that he had been on the blood cleaner so Dr Mike said 'give me some of those, I've got to test them on some of my patients – I don't believe you'. He did, and they worked.

Now, in Colorado, blood is considered 'toxic waste' or hazardous waste. It must be picked up and disposed of by incineration by registered toxic waste disposal people. Dr Mike had thrown these three or four slides in a box underneath his laboratory table. He looked down at this box about twenty-seven days afterwards and checked the slides again under the microscope. That blood was still alive. The half-life of human blood on an unsealed microscope slide is between two and a half to four days maximum. Twenty-seven days had gone by and the red cells were swimming in the plasma exactly the same as the minute he had drawn that blood. It had not crenated (serrated around the edge) – a fibrin reaction had not set in although it had evaporated around the edges. Now let's get to the point. One month after that, that is some fifty-one days later, those slides had not yet been picked up for disposal, so Mike checked them again. The blood had 'circled the wagons': there was about a half a millimetre spot in the middle where the cells had not evaporated and were still alive.

The people in his practice who had been tested upon with the blood cleansers have now got immortal blood. Now, what does this mean? If 'the adversary is within' he might not be a man with a red tail and horns out there somewhere with the number 666. Just as the Holy Spirit dwells within this temple, so might the adversary, at least the aliens which have been involved with us over many, many moons are in there and you can see them if you go to a dark-field microscopist, if you get rid of those, who knows what is going to happen? What happened to me. I was so fat that I was in a wheelchair and I had been given up for dead. The doctors who came to see me, friends of mine who were Medical Doctors who hadn't made a house call in Beverley Hills in thirty years, were coming down to my apartment saying 'Bob, you'd better dispose of whatever you've got – you'll never walk again. I was given so many tests. I brought Dr. Alexander Everett from Washington, paid his way, put him up in the *Red Lion* hotel. He worked on me until he said 'Bob, I'll have to go back now, there is nothing that anyone can do for you'. And I was in a wheelchair, but I'm sure as hell not dead! Everything is working well again.

My blood pressure when I started this averaged 219 over 190 and was borderline diabetic with blood sugar 425 to 475. Today my blood pressure is 130 to 140 over 70 to 75 and after just three weeks my blood sugar had dropped to 150, which at that time was considered normal.

So I'm here to share this information with you. I have nothing for sale. There are people who are selling things, I'm not one of them. Part of that is because I believe that God's work should be given freely. I expect to get my reward somewhere else if I don't come back to this planet of painful endeavour. I have a lot of theories about this and also the Food and Drugs Administration has come to my door with drawn guns at three o'clock in the morning. I have been beaten up by the people supporting the pharmaceutical houses who don't want a \$1.32 cure for AIDS.

Bob also speaks of his use of colloidal silver, (a document on which can be downloaded using the download link <http://www.free-energy-info.tuks.nl/Silver.pdf>) although Bob's method of production looks more simple. He says:

This is a glass of water which I got out of the kitchen. I've taken a single 9-volt battery and put a little "grain

of wheat" bulb (6 to 12 volt 55 milliamp) in series with the battery and these two silver wires. There is no known germ, bacteria or microbe which can survive what I am about to do right now. I'm going to put these two silver wires into this glass of water, about half an inch (12 mm) apart, and leave them there for about three minutes. That is all it takes. This is tap water and you can make this silver colloid for about one tenth of a cent per gallon and that is the most powerful medicine known to man. After three minutes Bob stirs the colloid with a plastic knife and demonstrates how a laser beam reflects off the microscopic particles of silver suspended in the water and then drinks the water. Bob drinks two or three glasses of colloid each day. The colloid prevents you from contract secondary infections during the first three weeks while you are getting well with the blood electrification process.

Finance: Money only has value when backed by something of worth. The largest purchase that most people make is buying a property. This is often done by taking out a mortgage with a financial institution such as a bank or a Building Society. For this, most people sign a mortgage agreement with the bank, agreeing to pay back the mortgage amount plus a large amount of interest, generally over a period of many years. If you default on the repayments, typically after many years of payments, the bank takes your property and sells it in order to gain as much money as they can. What you are not told is that the mortgage agreement is a contract and no contract is valid unless something of worth is offered by both parties and full disclosure of all circumstances is made. The bank does not offer anything of value as it just invents the money, creating it out of thin air and without any backing of something of worth. The bank regulations actually forbids the bank from lending out money deposited by it's members, so a bank cannot legally enter into any such mortgage agreement backed by the funds deposited with it. Further, no contract is valid unless there is a "wet ink" signature by both parties and a wet ink signature can only be made by a human. A bank cannot make a wet ink signature, nor can some other individual sign a contract on behalf of somebody else, so, no mortgage agreement is actually valid in law. Also, the bank being aware of this and not making it clear to you the mortgagee, is in breach of the "full disclosure" requirement of a contract, which is enough to invalidate the contract anyway. Therefore, if a bank tries to take your property for lack of payments, they are acting unlawfully and are not entitled to do so. They usually get away with it, because most people are not aware of the real facts involved.

The Media: You are expected to believe that the media is an honest and unbiased source of information. The reality is that all of the main media outlets are owned by just a few, very rich individuals, and their objective is **not** to provide unbiased reporting. It appears that they have three main objectives.

First, they want to make money and objective and truthful reporting does not necessarily help towards that goal. You will never, ever, find honest reporting of anything to do with free-energy or any other positive thing which individuals can do for themselves. For example, if a "report" is made on say, an HHO booster to improve mpg and reduce harmful emissions dramatically, it will be arranged that the supposed results show that these thing are not worthwhile. Contrast that with the reality that Dr Scott Cramton can use HHO gas from the electrolysis of water, to reduce the fuel requirement of any diesel engine by at least 60%. No matter how you try, no major news outlet will every report the honest facts as that could damage the excessive revenue stream of the oil companies.

Second, they want to generate as much fear and worry as possible because doing that over an extended period, causes the average person to be more amenable to having their freedoms taken away from them. It facilitates the introduction of surveillance on everybody, identity papers (birth certificate, driving licence, passport, social security number, voting register, National Census record, etc. – very much in the Nazi occupation style), going to war with countries which have never harmed you, considering people to be dishonourable just on the basis of their nationality, and the like. Try counting the items reported in the daily

news which are negative – murders, attacks, dishonesty, deaths through accidents, deaths through natural disasters, kidnappings, piracy, violence, environmental damage, etc. and compare that number to the count of positive things reported on – happy events, acts of kindness, successful ventures, etc. and see what ration you get, day after day, after day. This is not just sales being boosted because people love to read about disaster. Instead, it is a deliberate, long-term policy of psychological warfare against ordinary people.

Third, they deliberately divert the attention of people away from anything of real importance by promoting and encouraging excessive interest in things of no importance. There is a deliberate dumbing-down of almost all TV programs in the UK, the promotion of excessively violent video games, the promotion of trivia such as celebrities and their activities, dieting, gossip, fashion, and other irrelevant topics. They want you to give all of your attention to these things and not notice what is actually going on all around you.

Joseph Cater's Comments.

Joseph H. Cater has produced a book entitled "Ultimate Reality" which I find impossible to buy at any reasonable price level. In it, he points out many things which he supports with strong evidence. These things seem startling because, and only because, the present educational system deliberately encourages us to believe things which are clearly not true. Google books have a partial copy of the "The Ultimate Reality" at:

<http://books.google.com/books?id=ySsNiCPUecC&printsec=frontcover&dq=the+ultimate+reality+cater&cd=1#v=onepage&q&f=false>

The things which Joseph Cater states are so unusual that it would be easy to write him off as a crank. However, he backs up what he says, with a considerable body of realistic evidence which makes it very difficult to ignore what he says, in spite of the fact that most of his findings flatly contradict what we have been taught from an early age, and so accept as being reality. Whether or not you accept what he says is entirely up to you, but it is difficult for an honest person to reject his presentation out of hand.

He puts forward a strong case for there being a deliberate programme of scientific misinformation and suppression aimed at keeping the general public completely ignorant as to the actual physical realities of the solar system and the universe in general, and as a result, reality is very far from the popular conception. Mr Cater's description of matter provides reasoned explanations for a whole range of anomalies which conventional science can't adequately explain, and he quotes numerous experiments which provide firm evidence that what he is saying has a substantial basis in fact.

Here is a very brief summary of some of what he says in his book "The Ultimate Reality":

The biggest single factor is in the erroneous theory of sub-atomic particles. Mr Cater states that reality is actually much more simple than conventional theory suggests. The universe is filled with a range of energetic particles which he describes as "higher order ethers" and "lower order ethers". These ether particles are in continuous random movement at different frequencies and they produce a number of different kinds of composite particles including "Hard electrons" (with which we are already familiar) and "Soft electrons" which have very different properties. Soft electrons can draw hard electrons into themselves, masking the properties of those hard electrons. Combinations of ether particles form photons and all matter is composed of photons and these ether particles.

The operational forces which govern all matter in the universe are only electrostatic force and magnetic force, and the actions of both of these are modified by many different combinations of the two types of electron. As light is composed of photons and as they interact with the two types of electrons, many observed scientific facts have led to wholly incorrect deductions. Mr Cater indicates that the New World Order "elite" carefully foster and support these false conclusions, suppress information and physically alter observations before they reach the public. Mr Cater points out a number of instances where the alteration of data has not been sufficient to suppress the facts.

It is not possible to mention all of the points which Mr Cater makes, so please understand that the following is only a minor selection from a cohesive whole and much of the supporting evidence which he provides in his book is omitted here.

Mr Cater says:

1. The current theory of gravity is completely wrong, and gravity is caused by a component of the electromagnetic spectrum of about one trillion cycles per second (0.3 to 4.3 mm wavelength; located above

radar and below the infra-red region). The theory of gravity put forward by Sir Isaac Newton does not account for the **amount** of deflection of a plumb bob near a mountain. An asteroid as small as 150 miles in diameter, can have a surface gravity about the same as Earth's and some asteroids have moons of their own orbiting around them. This would be impossible if Newton was right.

As a result of the real cause of gravity, our Moon has a much higher surface gravity than was expected, (and consequently, a serious atmosphere). NASA had a major problem with the lunar landing of 1969 because if the real facts became known, then it would demonstrate that a major section of physics, as it is currently presented, is incorrect and they want to keep things exactly as they are at present. The Moon, in common with most planets, is not solid. When part of the lunar lander was dropped back on to the surface of the Moon, a seismic detector left on the surface showed that the Moon vibrated like a bell for about an hour afterwards. That would not have happened if the Moon were solid.

There is very clear evidence that NASA has censored the Moon landing very heavily, but their attempts at suppression have been flawed and some obvious pointers exist. For example, NASA claimed that the space suits of the astronauts weighed 185 lbs when on Earth. Photographs exist, showing an astronaut leaning over backwards and then regaining his balance. That would be a physical impossibility even under reduced gravity, and this implies that the "life support" systems were actually empty and not needed because there is an atmosphere. The high surface gravity is also seen when the astronauts ran. Even the slowed-down version released by NASA can't conceal the length of the steps and the height off the ground which are the same as they would be on Earth.

If the Moon had one sixth of the Earth's gravity as is claimed by conventional science, then the point at which the gravitational pull of the Earth balances that of the Moon would be about 22,000 miles from the Moon. The Encyclopaedia Britannica states this distance as being about 40,000 miles, which agrees with various other sources. That could only be so if the Moon's surface gravity were much higher than the supposed one sixth of Earth's gravity.

On more than one occasion, an Apollo astronaut tripped and fell on his face. Under one sixth gravity, that just would not happen, especially with a fit and active astronaut. Also, the rover vehicle used in later landings was 10' long, 7.5' wide and 4' high with 32-inch diameter wheels. The Earth weight was 460 pounds and under one sixth gravity, that would only be 75 pounds, but the astronauts had great difficulty unloading it from the lunar module. Engineers on Earth had already determined that to operate under one sixth gravity, the rover would have to be 20' long and have a 20' tread. With a loaded earth weight of 1,600 pounds, it would need a turning radius of well over 80 feet to avoid tipping over at 10 mph or more than 20 feet at 5 mph and descending steep hills would not be possible without major problems. But, the astronauts did descend steep hills and they made very sharp turns at maximum speed.

One of the photographs brought back by the Apollo 12 trip, showed an astronaut carrying instruments hanging from a bar. The instruments had an Earth-weight of 190 pounds, supposedly 31 pounds on the Moon, but the pronounced bowing of the bar would not have been caused by just 30 pounds.

During the early Moon trips, the astronauts stated that when they left the atmosphere, the stars were not visible. This is understandable as the atmosphere scatters starlight, making stars appear larger and so become visible to the naked eye. Outside the atmosphere, there is no scattering and the stars are too small to be seen without a telescope. On the Apollo 11 trip, shortly before reaching the Moon, Collins stated "Now we're able to see stars again and recognise constellations for the first time on the trip. The sky's full of stars ... it looks like it's night side on Earth". This demonstrates that the Moon has a significant atmosphere caused by much higher gravity than one sixth that of Earth, although the refraction of light through that atmosphere is less than the refraction caused by Earth's atmosphere.

Mr Cater points out that NASA is well aware of the real nature of gravity and had electrogravitic drives long before the 1969 Moon shot. Not only that, but due to the fact that the Moon is bigger than currently believed, further away and possessing a higher surface gravity, that rocket power used during the flight was supplemented by an electrogravitic drive. Any honest person who has studied the evidence is well aware that there are many craft with electrogravitic drives and most of these seen in the last sixty years, are man-made. (All governments are very keen to suppress this information as national boundaries could not be maintained if electrogravitic drive vehicles were available to the public).

2. Relativity, proposed by Albert Einstein, is not correct and Mr Cater spends quite some time demonstrating that relativity is wrong. Prior to Einstein, the Transverse Wave Theory of light was universally accepted. Waves cannot exist without a medium which vibrates in some manner to transmit them. Therefore, the "ether" which permeates all of the universe was accepted. The Michelson-Morley experiment was set up to

test this. A ray of light was split into two parts which were made to traverse different paths of equal length. The motion of the Earth through the ether should then cause the recombined rays to show diffraction patterns. They didn't. It did not occur to anyone that if light were retarded by passing through the ether, then bodies such as planets would be seriously retarded by their passage through it and would slow down and stop. This experiment also gave rise to the ridiculous idea that the speed of light is a constant, in spite of the well-known fact that the speed of light through water is only 75% the speed of light through space. It was also proposed that the speed and direction of movement of an observer didn't matter, That time slows down on a moving system, that a body will shorten in the direction of motion and that the mass of a body will increase the faster that body moves. These are ridiculous suggestions. The famous $E = mc^2$ equation was actually derived from the Lorentz equations in 1903, two years before Einstein got into the act.

Physicists argue that particle accelerators demonstrate the increase of mass with speed. This is not the case and the experiments actually demonstrate a very important principle which provides a better understanding of many physical phenomena. It is an established fact that a magnetic field develops around a charged body when it is given a velocity. Where did the magnetic field come from? In the particle accelerator, as the particles accelerated, magnetic fields developed around them. As the total energy of the system remains constant, the magnetic field must have developed at the expense of the electrostatic field - the transformation of one kind of energy into another kind. This conversion from repelling electrostatic charges to magnetic fields causes the particles to clump together, giving the false impression of an increase in mass. Further, as the electrostatic component drops to almost zero, the accelerating force diminishes to near zero also, giving the false impression that a material body can't travel faster than the speed of light. The reality is that bodies can travel many times the speed of light.

According to General Relativity, a gravitational field will tend to slow the passage of time and the stronger the gravitational field, the more marked the effect. It was found that Caesium clocks run faster at high elevations than they do at ground level. This has been taken as a proof of the validity of Einstein's ideas. The concentration of soft particles is higher near the ground than at high elevations and that makes clocks run faster at high elevations. As to the speed of light not depending on the velocity of it's source, the Sagnac experiment of 1913 provides direct proof that the observed velocity of light **is** dependent on the velocity of it's source, disproving Relativity. Mr Cater provides extensive demonstrations (as do other people) that Einstein's deductions are not correct.

3. It is clear that gravity is responsible for the tides, but the standard explanation is wholly inadequate, being based on the assumption that gravitational effects have unlimited penetration. In other words, the only attenuation when passing through matter is due to the inverse square law, which actually would be a violation of the law of conservation of energy.

It is well known that a body cannot be given an acceleration relative to another body if both bodies experience the same acceleration. It follows then that since large bodies of water are accelerated relative to the Earth to cause tides, the water is being experiencing a different acceleration than the Earth as a whole, otherwise, there would be no tidal movement of water across the surface of the Earth. Assuming that gravity has unlimited penetration causes problems when accounting for tidal movements. Since the distances between the Sun and the Earth and the Moon and the Earth are large in comparison to the diameter of the Earth, all parts of the Earth will experience nearly the same gravitational attraction from these external bodies if gravity has unlimited penetration. High tides tend to occur when the Moon is at it's zenith, both directly underneath the Moon **and** simultaneously, on the opposite side of the Earth.

The Earth's orbit is inclined to the Equator by 28 degrees and so the Moon is never further North or South than 28 degrees. According to Newton's theory, the highest tides should occur near the Equator but the reality is that the highest tides are experienced much further away from the Equator, both North and South of it. Mr Cater provides an in-depth discussion of these effects, demonstrating that Newton's concept of gravity is wrong.

4. It is generally accepted that energy, in any form, flows from a higher potential to a lower one. The law of redistribution of energy states that when radiant electromagnetic energy interacts with matter, the resulting radiation as a whole, is of a lower frequency than the original light. This is why temperatures at lower elevations are generally higher than those at higher elevations, as sunlight passing through air converts to lower frequencies including infrared which activates the thermal motion of atoms and molecules, thus producing heat. Any dynamic unit is less active as a whole, than the individual parts comprising it. The higher ethers consist of the smaller, more active particles while the lower ethers are composed of the large, more complex and consequently less active particles. Both ethers occupy the same 3-dimensional space (which is the only space that there is).

When light of a given frequency range is produced, only the ethers associated with this light are directly activated. Light photons are composed of combinations of ether particles. Photons combine to form the penetrating particles which accompany this light. Particles composed of light in the lower frequency ranges are referred to as "soft" particles while those associated with gamma rays and above are referred to as "hard" particles.

Soft particles are more penetrating than the photons from which they are made, because, unlike the larger soft particles, photons have a relatively great surface area in proportion to their mass. Soft particles, and particularly soft electrons, play a vital role in all life processes and in other chemical reactions. The energy or field intensity of and around the higher ether particles is greater than that of the lower ethers. The diameter of a particle is inversely proportional to the average frequency of its constituent light.

5. The energies radiated from the Sun are continuously transformed into ever lower frequencies as they penetrate into the Earth. In this manner, nearly all of the original ultraviolet is transformed into lower frequency radiation by the time it penetrates the shell of the Earth. It is the transformation of some of the radiation from the Sun into gravity-inducing radiation which holds the Earth and the other planets in orbit around the Sun and give the illusion that the Sun has about thirty times Earth gravity. It should be mentioned that soft particles penetrate solid matter more readily than hard particles which are, of course, an integral part of matter.

All matter continuously radiates soft particles of many different kinds due to the interactions of the fundamental particles. These radiated particles undergo a transformation effect, according to the transformation law, when passing through large concentrations of matter. When this occurs, some of the radiation is transformed into gravity-inducing radiation. This is the source of some of the surface gravity of both the Earth and the Moon. The greatest contributing factor to Earth and Moon gravity is the transformation of radiation resulting from the thermal agitation of atoms and molecules. The particles resulting from this activity are comprised of lower-frequency photons. Such radiation is more readily transformed into gravity-inducing radiation because it is closer to this frequency band to begin with. A significant portion of this radiation, originating miles below the surface, is converted into gravity-producing energies by the time it reaches the surface. Most of the gravity radiation of the Earth and the Moon is created in the topmost fifty miles of their crusts. Below that level, much of the energy from the Sun has been transformed into softer particles, and that material of the Earth and Moon is permeated with them.

These soft particles screen out gravity radiation more effectively than solid matter does. This is because the ethers with which they are associated, are closer in frequency to the gravity radiation band. This explains why Moon gravity is nearly equal to Earth gravity. At the same time, it is clear why the Cavendish Experiment for determining the so-called "gravitational constant" was misleading – there wasn't enough material in the bodies used in the experiment to produce any radiation transformation. The gravitational effects produced by the bodies were due entirely to the thermal agitation of the molecules, without any transformation of radiation. The thermal agitation of molecules produces infrared and only an infinitesimal portion of this radiation is in the gravity-producing frequency range. This "gravity constant" plus the idea of unlimited gravity penetration, requires scientists to assume that the Earth has a tremendous mass and an iron core four thousand miles in diameter.

It is significant that some of the Cavendish Experiments indicated that gravity effects varied with the temperature. When the large sphere used in the experiments was heated, the smaller sphere had a greater tendency to move towards the larger sphere. When the larger sphere was cooled, the smaller sphere receded. This was explained away as being caused by convection currents although they failed to explain how convection currents could produce such an effect. A detailed account of this can be found in the 11th edition of the *Encyclopaedia Britannica* in the section entitled "Gravity". (If they felt that air currents were skewing the results, then the experiment should have been repeated inside a box which had the air removed).

As mentioned before, matter produces infrared radiations which are partially transformed into gravity radiations. In the case of mountain ranges, there is not enough matter to transform significant portions of such radiations into gravity radiations. Much of the radiation will escape from the tops and slopes of the mountains before they can be transformed, since their average heights are generally small compared to their horizontal dimensions. The gravity radiations produced deep in the interior of the mountains are partially dispersed by the overlying mass. This is the cause of the plum bob enigma which is a source of annoyance to conventional physicists because the plumb bob is not pulled towards the mountains to the extent demanded by Newtonian laws.

Another problem is that, in comparison to the Sun, the Earth radiates only an infinitesimal amount of

radiation per unit of surface area but it is able to keep the Moon in it's orbit around the Earth. Even allowing for infrared radiation passing from the Earth to the Moon and converting to additional gravitational radiation there, it still wouldn't be enough to keep the Moon in orbit unless the Moon were hollow and had a shell not more than a hundred miles thick.

In 1978, scientists were shocked to discover that some of the asteroids have moons which orbit around them at respectable velocities. According to Newton, this is impossible as the gravity of an asteroid would be far too feeble to allow this. When a body is a few miles across, it is large enough for gravitational radiation to be produced. This effect increases rapidly as the size of the body increases as far more infrared is transformed than is screened out by the outer layers of the mass. The effect continues until the body is about 150 miles in diameter and beyond that point, the screening effect of the outer layers keeps pace with the rate of increase of the transformation of infrared into gravity radiation. This means that all planets have practically the same surface gravity.

6. Mr Cater explains how soft and hard particles and the limited penetration of gravity account for Earth upheavals, continental drift, earthquakes and volcanoes. He also remarks that if the Earth were a completely solid ball and the Newtonian version of gravity were correct, then the Earth would be completely rigid and no Earth changes would occur other than some minor erosion, and there would certainly be no mountains left by now.

7. One of the most fundamental physical laws involves the relationship between the electrostatic and magnetic fields. One transforms into the other and vice versa. Inertia is a third factor involved in the relationship between the electrostatic and magnetic fields. The kinetic energy of a moving charge is manifested in it's magnetic field. The magnetic field increases at the expense of it's electrostatic field (as dictated by the law of conservation of energy). The role of inertia and the conditions governing it's magnitude are now apparent. The inertia of a body is dependent on it's ability to generate a magnetic field when it is given a velocity. The greater the inertia, the greater this ability.

The magnitude of the inertia of a body is directly proportional to the energy of the magnetic field which the body develops for a given increase in velocity. It follows then that inertia is dependent on the total electrostatic charge of a body. This is also true for so-called "uncharged" matter. In the supposedly uncharged state, all atoms and molecules have a net positive charge. Therefore, even atoms and molecules develop a magnetic field when they are given a velocity.

In 1901, Max Planck found that he could only derive the correct distribution in frequency of the radiant energy in the cavity of a black body as a function of the temperature of that body, if he assumed that energy exists in discrete units. He came up with $Nh\nu$ where N is an integer, ν is the frequency of the light involved and h is a universal constant (expressed in terms of energy multiplied by time, that is, erg-seconds). This is now known as Planck's Constant and is 6.6×10^{-27} erg-seconds.

The kinetic energy of a light photon is inversely proportional to the frequency. The lower frequency light, consists of larger and more massive photons travelling at the same velocity as the higher frequency photons. On average, the number of photons in any given ray, and the number of accompanying soft electrons will be a constant, regardless of the frequency. This is in accordance with the conclusion that the average distance, or mean free path between ether particles of the same kind, is a constant, regardless of the ethers involved. The average number of photons comprising a soft electron will also be independent of the frequency. This means that the diameter of the surface area of a soft electron, will also be inversely proportional to the frequency. Soft electrons accompanying light, travel at a velocity which is less than that of light. The soft electrons pick up speed, by bombardments of faster moving photons.

From a superficial glance, it seems that the average velocity of soft electrons should be independent of the frequency of the light associated with them. This is not so. The soft electrons associated with the higher frequency, travel at a higher velocity, and herein lies the key to the photo-electric effect. Although the lower mass of the higher frequency soft electrons is offset by the lower kinetic energy of the bombarding higher frequency photons, the surface area is greater in proportion to mass. This means that in proportion to mass, the electrons associated with the higher frequency light will receive a greater bombardment of photons and so, a greater accelerating force. The ratio between surface area and volume, or mass, is inversely proportional to the ratio between the diameter of two given spheres. Since the other factors balance out, it follows that the resultant average kinetic energy of soft electrons in proportion to mass, is directly proportional to the frequency of the light with which they are associated. As soft electrons collide with a surface, the hard electrons which they contain, are released and they bombard the surface, producing the photo-electric effect. They will be travelling at the same velocity as the soft electrons which housed them, so their average kinetic energy will be proportional the frequency of light.

Quantum mechanics is considered the most monumental achievement of twentieth century physics. In view of the principles presented above, it is not surprising that mathematical juggling with Planck's constant would account for many experimental results (in a quantitative sense). Quantum mechanics experts have enjoyed considerable success in this respect, especially in the realm of atomic spectra, without knowing why. In reality, quantum mechanics does not even qualify as a theory or a concept. It is merely an attempt to give mathematical descriptions of certain phenomena with Planck's constant and his valid assumption as a starting point. Modern "theoretical" physicists have absolutely no conception of why their mathematics agrees with certain experimental results. Yet, they have led themselves to believe that by giving mathematical descriptions of such phenomena, they have actually explained them.

It now becomes evident, why a mass can travel through space at a constant velocity, and encounter no decelerating force. The ether particles are so active that the closing forces at the back of the moving body, tend to equal the resistive forces encountered at the front. The rear portion creates a temporary void which is rapidly filled in by the surrounding ether particles, producing an effect very much like the Coander Effect. During the filling in process, the fundamental particles comprising the rear of the body are bombarded with ether particles travelling at a higher velocity than is normal. Also, the ether particles of which the mass is comprised are so relatively sparsely distributed throughout space, the situation is equivalent to a great mass travelling through a highly rarefied atmosphere.

8. During the creation of a photon, the ethers in the vicinity are suddenly compressed. Some of the ether particles are forced close enough together to adhere to each other. This aggregate is then propelled outwards with great force in a manner similar to a compressed spring being released. The photon reaches the speed of light after this accelerating force has been expended, which happens in a distance equal to the so-called wavelength. This process is repeated in the same region and another photon is produced which follows the first one, just one wavelength behind. A wide range of ethers are periodically affected during the production of ordinary light. This results in a countless variety of such particles being propagated in all directions with many different wavelengths. Since many photons are projected in all directions, many collisions will result, causing a significant portion to adhere to each other in aggregates.

The great majority of soft electrons are created during fluctuations in light velocity when passing through media of varying density, and even in it's passage through outer space. Any slowing down, produces a backing up of photons and a consequent combining into relatively huge aggregates. In the beginning, these aggregates move much more slowly than the free photons. Consequently, some of the photons which were created at a later time, catch up and adhere to the aggregate. Their collisions with the aggregate particles causes the particles to speed up. This is the origin of the particles which always accompany light. Particles formed in this manner will vary greatly in size, stability and penetrating ability. It has been shown that soft particles will penetrate ordinary matter more readily than the hard particles. So, ether particles combine to form photons which in turn, combine to form light particles. This, light particles will disintegrate into photons.

A typical beam of light
made up of photons and soft particles

Atoms are comprised of hard particles which are uniform in size and structure and it follows that they were produced by an entirely different process. When light enters a medium, it encounters a conglomerate of soft particles created by the activities of the fundamental particles of the atoms which comprise the medium. This causes the light to slow down and the particles of light to crowd together inside the medium. If a beam of light enters a medium at an angle, the portion entering first will travel a shorter distance than the rest of the beam during the same interval of time. The portion of the beam entering the medium later is pulled by magnetic attraction of the particles, towards the side which reached the surface first. This causes the beam of light to be bent or change direction, accounting for the refraction of light which has never before been adequately explained.

Mr Cater then goes on to resolve the famous wave-particle paradox, and he also points out that the famous Michelson-Morley Experiments actually disprove the Transverse Wave Theory of light.

9. It must be realised that nature's laws are basically simple. To gain a deeper understanding of the nature of electrons, protons and electrostatic forces, it is necessary to look for an uncomplicated picture of the fundamental particles and the cause of their behaviour patterns. The collision laws involving the molecules of a gas can be applied to the ethers. Also, it can be deduced that electrostatic forces are the result of an imbalance of ether particles bombarding fundamental particles of matter.

It seems logical to assume that electrons and protons have a spherical shape as a sphere is the most stable and efficient geometrical form. It also has the smallest surface area for any given volume. However, such an assumption leads to insurmountable difficulties. Electrons and protons have a preferred direction of spin in relation to their direction of motion. The electron follows the left hand rule, while the proton spins according to the right hand rule. With a perfect spherical shape they could not have any preferred direction of spin. However, the preferred directions of spin can be readily accounted for if the particles are pear-shaped or egg-shaped and they are hollow.

When ether particles have a preferred direction of motion away from the electrons due to reflections, a pulsating electric field results. The excessive flow away from the electron tends to reduce the bombardment of incoming ether particles. A temporary low ether pressure around the particle is a result of this and in turn, this reduced pressure reduces the reflections and that causes the ethers to move in again and a sudden increase in ether bombardment results. This is something akin to the Coander Effect. The cycle is then repeated. It is to be expected that an electrostatic field is no exception and in this respect, "electrostatic" is a misnomer. The fluctuations are at such a high frequency that experimental results will see the (average) force as being a constant.

The behaviour of beams of electrons and protons in strong magnetic and electric fields indicates that protons have about 1836 times the inertial mass of electrons. Inertia is directly proportional to charge, indicating that the total charge of a proton is 1836 times as great as that of an electron. The idea that the hydrogen atom consists of one electron and one proton has never been questioned. To quote from a science magazine: "When protons crash into each other, they release showers of electrons, which suggests that protons are made up of particles more basic than themselves".

On the basis of relative charge effects alone, it follows that a hydrogen atom, instead of having only one electron orbiting a proton, that there are at least 1836 orbiting electrons. However, since the proton has relatively little movement in comparison to the electron, a far greater percentage of the electrostatic field of the electron has been transformed. This means that in order for the hydrogen atom to have close to a neutral charge, there must be thousands of electrons in one hydrogen atom. This seems to create a paradox as the amount of electricity required to liberate a given amount of hydrogen in electrolysis indicates that only one electron is necessary for every atom of hydrogen.

Scientists have never comprehended the source of the electricity that powers electrical equipment. There are unlimited quantities all around us, permeating all of known space. This hard electricity is camouflaged by softer particles which are also distributed throughout space. The flow of this limitless source of electrons can easily be set into motion. The electricity employed in electrolysis merely triggers the flow of far greater quantities. Also, when a hydrogen atom is ionised, it only needs to lose a very small percentage of its electrons instead of being reduced to only a proton.

Matter is rendered visible by the steady formation of soft particles generated by the activities of the fundamental particles. It is then apparent that frozen hydrogen would be completely invisible if electrostatic fields were not cyclic and the hydrogen atom had only one electron. Cyclic electrostatic fields are largely responsible for the complex spectral pattern of all of the elements. The cyclic pattern of hard-particle interactions is complex. This complexity increases rapidly as the number of fundamental particles in the atom increases.

Since electrons move at much higher velocities in the atom than protons do, they cover much more territory and so a higher percentage of their electrostatic charge is transformed into magnetic energy. This means that the positive charge in the atom will overbalance the negative charge and so, give the atom an overall positive charge. This explains why electricity tends to move towards ground and the Earth must possess a positive charge.

The electrostatic field effects near the atom in close proximity to the electrons, will be negative. Moving outwards, this negative effect diminishes quickly and a zone of positive field effect exists. The position and intensity of these zones, determines in part, the chemical and physical properties of the atom. There are regions where the atoms will attract each other and regions where they will repel each other. Ether particles have a similar structure and follow the same pattern.

The velocity of orbiting electrons in atoms is not uniform. There are periodic fluctuations resulting from mutual interferences within the atom itself and from adjacent atoms, in addition to the pulsating electrostatic fields. It must be noted that the properties of the atom are not observed individually, but as a collective group. The region of activity for the protons is relatively small and a significant number of electrons are trapped here. This region is the origin of neutrons, which are actually collapsed hydrogen atoms. It is interesting to note that when hydrogen is subjected to ultra high pressures, it behaves like a high concentration of neutrons and passes through the container which is being pressurised as though it didn't exist.

A more detailed discussion of the structure of the neutron is in order. The new concept of thousands of electrons comprising the hydrogen atom (to say nothing of the other atoms), provides, for the first time, a means of accounting for the properties of the neutron.

When a cloud of electrons orbiting the proton is forced into close proximity with the zone of repulsion, as described earlier, their motions become restricted. As a result, there is a lowering of the average velocity with a consequent increase in their negative electrostatic charge. This provides a stronger bond between the proton and the electrons. The orbital speed cannot be increased because of the zone of repulsion surrounding the proton, and the crowding of the electrons. The higher overall negative charge of the electrons almost completely cancels out the positive charge of the proton. The result is a particle which is electrically neutral, as far as most experiments can determine.

The electron cloud comprising the hydrogen atom is further removed from the proton and the individual electrons are not restricted in their orbital motions. The average velocity is much higher and consequently, the hydrogen atom has a high positive charge. The atoms of the gaseous elements, such as hydrogen and oxygen, are highly magnetic. Therefore, two atoms combine in much the same way as two bar magnets, to form a molecule consisting of two atoms. This is the reason why the molecules of nearly all the gaseous elements consist of two atoms. The combination has a still higher overall positive charge than a single atom has. As a result of this, the molecules have a strong mutual repulsion which keeps them widely separated at normal temperatures and pressures. Thus, they remain a gas even at extremely low temperatures.

The presence of electrons in the “nucleus”, nullifying repulsive forces, along with the magnetic fields resulting from the motions of neutrons, is the major source of the so-called “mysterious force holding the nucleus together”. In reality, the pinch effect of magnetic fields is the prime force which holds the atom together. Orthodox physicists have complicated the picture by claiming that many different forces exist: magnetic, electrostatic, gravitational, nuclear, and others to which they have ascribed odd names. In reality, only electrostatic and magnetic forces exist and there are two, and only two, basic particles – electrons and protons. Since the electrostatic field effects around the electron and proton are cyclic, the magnetic fields which they generate will also have a cyclic intensity.

10. Although neither spin when at rest, both the electron and the proton start to spin in a definite direction when they are given a velocity. This is contrary to the assertions of modern theorists who talk about particle spin with reckless abandon. The electron always follows the left-hand rule, while the proton follows the right-hand rule.

When placed in an electrostatic field, they move in such a manner that the large end is facing in the direction of their motion, regardless of their original orientation. The reason for this is not difficult to discern. If they are hollow and the shell is of a certain thickness in proportion to its diameter, then the larger end will have more surface area in proportion to its mass than the smaller end will have. The thickness of the shell at the smaller end will be much greater in proportion to its diameter. This means that ether bombardment at the larger end will tend to give it a greater acceleration than that imparted to the smaller end and as a result, the larger end will be forced ahead in the direction of motion.

The picture is still incomplete. In order for the particle to have a preferred direction of spin, the frontal surface must be grooved in the manner of a right-hand or left-hand screw. Such a shape is consistent with recent experiments at the *Argonne National Laboratory*, which studied the shattering of proton beams aimed at target protons. The results indicated that protons are not spherical. A detailed account of such experiments can be found in the article “The Argonne Experiments and The End of Quarkery” by Eric Lerner which appeared in the Oct-Nov 1997 issue of *Fusion Magazine*. In the article he showed that some of the basic assumptions of quantum mechanics are contradictory, and he dispensed with the popular theory in particle physics which assumed an ever-growing family of hypothetical particles called “quarks”.

It has been noted that a magnetic field surrounds a moving charge. The magnetic lines are in the form of circles. An electron or proton tends to carry ether particles around with it in a circular motion as it moves through the ethers. This is due to the mutual repulsion between the ether particles and the ether particles comprising the particle. The reactive forces cause the particle to spin and they produce a vortex motion in the ether itself. The greater the velocity of the particle, the faster it spins and the more ether particles are caused to flow around it in the direction of the spin. It is this flow of ether particles around a moving charge which produces the magnetic field effects observed. A three-dimensional view of this magnetic field shows that it resembles a corkscrew spiral or vortex.

The ether particles which would normally cause repulsion between two adjacent particles at rest, spin when they both move and the electrostatic repulsion drops off and is replaced by a magnetic field which draws the two particles together. This effect is also seen in two adjacent wires carrying a heavy current flowing in the same direction. The wires are drawn towards each other.

If two unlike charges move along together, they spin in opposite directions, generating magnetic fields of opposing polarity which tends to push the particles apart.

An electron or proton moving in a magnetic field has two forces acting on it. One force tends to push it down the magnetic lines of force because of excessive ether particle bombardments in one direction of flow. The other force is perpendicular to the lines of force. If the velocity of the particle is high, then the latter force is by far the more significant. This force is a result of Bernoulli's principle. Magnetic fields tend to capture large quantities of soft electrons.

11. The conventional theory of geomagnetism lacks merit. According to it, the major portion of geomagnetism is the result of electric currents flowing in a molten iron core 2,000 miles beneath the surface of the Earth. Even if such a core did exist, the conclusion would still be false. Scientists are somewhat vague as to how a magnetic field could extend 2,000 miles beyond an electric current considering that it takes a very powerful current to produce even weak magnetic effects a short distance from the current flow. The electrical resistance of iron at the alleged temperatures of the core would be staggering, which raises the question of how the necessary massive potential difference is produced to drive a large current in the core in the first place.

A great wealth of evidence supports the conclusion that geomagnetism is produced by the Earth's rotation. The intensity of the field is dependent on the concentration of negative charges in the atmosphere and the crust and on the rotational velocity. Since the concentration of charges in the atmosphere fluctuates in a 24-hour cycle, the magnetic field can be expected to fluctuate accordingly. This is an established fact.

Supposedly uncharged atoms and molecules are not electrically neutral, but possess a positive charge. It has always been assumed since the days of Newton, that inertia is directly proportional to mass. This has been shown to be incorrect as inertia is dependent on total charge and is therefore independent of mass. It follows that an atom has less inertia than any of the fundamental particles of which it is composed. The small overall charge of an atom is the result of the equalising of positive and negative charges. It's slight ability to generate a magnetic field for a unit increase of velocity is due to electrons following the left-hand rule while protons follow the right-hand rule. The inertia of an atom is limited because the magnetic fields of the electrons and protons from which it is constructed, cancel each other out to a major degree. Stripping electrons from an atom will give it a strong positive charge and much greater inertia even though it now has less mass. Adding electrons to it can also raise it's inertia if the extra electrons cause it to end up with a greater overall charge than it had before. The Nobel Prize winner Gabriel Lippman confirmed this when he found that bodies in a charged state have greater resistance to acceleration than they have in their uncharged state.

Since matter behaves like a positive charge, it follows that gravity radiation will accelerate positive charges in a direction opposite to that of the direction of its propagation. A gravitational field repels negative charges. When the hair on a person's head is given a strong negative charge, it stands straight up due to the negative charges on the hairs carrying the hairs with them as the charges are pushed upwards by gravity.

The bulk of the radiations and soft particles of matter cover only a relatively narrow part of the electromagnetic spectrum. They are produced by the interactions of the fundamental particles of the atom in addition to the interactions of the atoms themselves. Incidentally, it is the soft particles comprised of photons close to, and in, the visible range which permeate matter that make matter visible. If only the hard particles were present, solid matter would be invisible, although completely tangible.

The leading part of the gravity radiation front produces negative charge effects, while the trailing portion which has passed a given body must have substantially reduced negative charge effects. The spin of the particles in gravitational radiation have a gyroscopic effect which keeps the particles orientated in the same position and the particles have little tendency to scatter.

The faster moving photons overtake the soft particles and tend to adhere to them in irregular patterns, creating a perforated and extremely rough surface on this part of the particle, not unlike that of a positive charge. This has a tendency to cancel out much of the negative field effects on this part of the particle. The bombardments accelerate the particles to such an extent that no more photons can adhere to them. Therefore, the rear part maintains a positive charge, or at least, a much reduced negative charge.

Another important factor which contributes to a reduced negative charge at the rear is that there is a far greater photon concentration in this region than exists at the frontal portion. This is a result of a backup of photons caused by the lower velocity of the soft particles accompanying the radiation. This photon concentration tends to divert the normal ether bombardments (which produce the electrostatic effects) from their usual paths. Since gravity radiations produce forces, it follows that there are interactions which eventually disperse the radiation, accounting for the limited penetration of gravity radiation. Gravity is an electrostatic effect, not some space warp or mysterious force with imponderable properties. If matter is impregnated with sufficient quantities of negative charges, especially soft electrons, it will become weightless and even levitate.

Some individuals have the ability to do the reverse of levitation, possibly by expelling large quantities of negative charge from their bodies. A dwarf who had a normal body weight of 123 pounds demonstrated under strict anti-fraud conditions that he could increase his weight to 900 pounds.

The physics of levitation was demonstrated in part when missiles were found to have lost most of their original weight after travelling through the Van Allen Radiation Belt and returning to Earth. The weight loss continued for some time and containers in which pieces of the missile were placed, also lost weight. The radiation belt contains high concentrations of negative charges of all kinds, from hard electrons to the very soft ones. The missile became impregnated with negative charges as it passed through this region, absorbing an abnormal quantity. The more penetrating softer particles opened the door for the harder particles to enter. The loss of weight of the container would have been caused by the missile gradually losing some of its excess negative charges and those charges being absorbed into the container.

12. Faster than light travel is possible because the accelerating gravity beam travels with the mass being accelerated. At ultra-high velocities, or where most of the electrostatic potential of matter has been transformed, cohesive forces will tend to break down and the material will cease to be a cohesive solid. However, spaceships can travel many times the speed of light provided that the ship and the occupants are impregnated with the right combination of negative charges which would prevent any extensive transformation of the electrostatic mass into magnetic energy. At ultra-high velocities, the closing forces on the rear of the craft no longer compensate for the forward resistance, so it requires a steady application of accelerating forces to maintain velocities many times that of light.

The evidence concerning spaceship propulsion demonstrates that the famous Einsteinian equation $E = mc^2$ falls far short of representing the energy potential of matter. From the kinetic energy equation $E = 0.5mv^2$ it follows that a body travelling at only 1.5 times the speed of light (which isn't even a cruising speed for most spaceships) has a kinetic energy which exceeds the value of Einstein's celebrated equation. At this velocity, only a miniscule part of the energy potential of the mass has been released. The meaninglessness of the famous equation is also evident, because inertia is dependent only on net charge and not necessarily on mass or quantity of material.

13. Another item which demonstrates the validity of the information presented here is the fact that determinations of the gravity "constant" "g" is always significantly higher when measured in mines. This is to be expected as the soft electron concentration is much higher below the surface than it is above the surface. Another fact which disturbs physicists (and consequently given little publicity) is that objects at the bottom of mine shafts weight significantly less than they should according to Newton's concept of gravity.

Another enigma which is damaging to the academic viewpoint is that experiments indicate that gravity doesn't impart the same acceleration to all substances. To try to deal with this fact, they have to introduce a mysterious fifth force which is supposed to be an extremely feeble repulsive force with a limited range. It is supposed to be more prevalent in some substances than in others. The concepts already explained here show that this is to be expected. Different atoms and molecules have different total positive charge effects in proportion to the number of fundamental particles from which they are made. Consequently, they will not be given the same gravitational acceleration even if the mass is identical.

14. We now come to questions such as; How does the law of redistribution of energy work? What are the real principles behind colour perception? Why is the velocity of light independent of its frequency? Why is this velocity equal to the ratio between an electromagnetic and electrostatic unit of charge? The answers to

these questions have never been given before.

When materials are subjected to high temperatures, great fluctuations occur in the velocity of electrons in their orbits. This in turn, creates interactions and interference effects between electrons moving in opposite directions inside atoms and between electrons in adjacent atoms. These interactions generate changes in the electrostatic field effects of the electrons, which will cause regular and distinct changes in their so-called orbits. This is because the charge on the electron varies with its velocity. Abrupt changes in the velocity of a particle disrupt the ethers which results in the formation of photons.

The larger the atoms, the more complex the interactions, and consequently, the more intricate the spectral pattern. The photons comprising the electrons, determine the range of the ethers which will be disrupted. These ethers are intimately connected with the electrostatic field intensity of the electrons. Thus it follows from this new definition of Planck's constant, just why this definition must be taken into consideration in all of the calculations concerning the frequency of light produced in interactions.

The electrostatic field effects around an electron depend on the range and level of the ethers deflecting off the sides of the particles. This range is not necessarily the same as the range of ethers affected by sudden changes in the velocity of the electrons, but there is a direct correlation between the two. Planck's constant has a role throughout the procedure as all ether particles have the same kinetic energy.

The law of redistribution of energy states that when light interacts with matter, new light with a lower average frequency than the original is produced. One of the most simple demonstrations of this is shining a blue or violet light through a large number of filters of any type. The emerging light is always red. All of the colours which we normally see are combinations of different frequencies of photons. A wide frequency range of soft particles and photons will tend to be grouped together. This means that bands of light in the blue, indigo and violet ranges will contain other colours down to the reds, although the reds will make up only a very small percentage. The human eye sees only the dominant colour, and prisms cannot separate them. The colour experiments of Edwin Land proved this to be the case.

In the May 1959 issue of *Scientific American*, Land showed that two black and white transparencies produced from black and white film, were exposed to filtered light from two different (reasonably spaced apart) parts of the spectrum, the resulting superimposed images were in full colour. This shows that it requires subtle combinations of frequencies for the eye to perceive colour if the light isn't in a narrow frequency band. Otherwise, the eye will see things in various shades of black and white, which contain all the colours but in the wrong combinations to be seen as colours. This is what occurs for people who are subject to 'colour blindness'.

Under certain conditions, light reflected from a mirror can have greater intensity than the incoming light. The light has to be of high intensity. When the particles of the incoming light collide with the mirror, those that are reflected are instantly brought to a halt. This produces a tremendous disturbance of the ethers which results in the creation of new photons which are added to the photons which are reflected. In addition, many of the photons reflected and created, combine to form soft electrons, and so the reflected light has a higher percentage of soft electrons than the incoming light beam.

It follows that repeated reflections of a light source such as the Sun, would result in a highly lethal laser-like

beam. This has been demonstrated on numerous occasions. Perhaps the most notable demonstration occurred near White Sands, New Mexico in the early 1950s. It was witnessed by an acquaintance of a personal friend of Mr Cater's, and it was something which he wasn't supposed to have seen. About thirty-five four foot diameter mirrors were arranged so that the resulting beam was directed at the rock wall of a mountain. It immediately created a neat hole through 200 feet of solid rock.

An associate of Mr Cater's found that by putting a strong negative charge on the mirrors that their reflective power is considerably increased. He charged a series of metallic mirrors to 20,000 volts and found that after 10 repeated reflections from the Sun, the resulting beam was very lethal. This shows that it is the negative charges deposited on a mirror surface which enables it to reflect most of the light that falls on it. Incoming light immediately deposits negative charges on the surface and those charges repel the rest of the light. The more intense the incoming light, the higher the concentration of negative charges placed on the surface. This accounts for the fact that highly lethal beams reflecting from the surface do not destroy the mirror. The mirrors must be metallic and preferably concave. Glass mirrors do not work as much of the incoming light is lost before it reaches the reflecting surface and much of the shock effect of the light reflection is lost due to the glass slowing down the incoming beam. The incoming light must strike the mirror in as nearly a perpendicular direction as is possible. If soft electrons associated with colours known to be highly beneficial could be concentrated using this method to produce rapid healing

15. The question arises: Why is the velocity of light independent of it's frequency? This is implicit in Maxwell's equations but it still isn't explained. When the ethers are disturbed to produce a photon, a fraction of them are compressed and a great number are forced close enough together to adhere to one another. The higher the ethers affected, the more rapidly and suddenly this displacement has to occur in order for a photon to be produced, otherwise, the ether particles will escape this compression since they are very active. This momentary compression quickly returns to normal, rather like a compressed spring being released. This rebound hurls the aggregate photon forward at the speed of light. The distance of this rebound is equal to the so-called wavelength, or distance over which the photon is accelerated to the speed of light.

This is exactly what happens when lower ethers are disturbed to form lower frequency photons, except that the rebound takes place over a greater distance with a lower average acceleration of the photon. Since the warped pattern is identical in both cases, both photons reach the same velocity, which is independent of the actual wavelength produced. As both photons receive the same thrust, it can be seen that lower frequency photons must have a greater mass, that is, the frequency of light is inversely proportional to the mass of the protons which form that light.

The behaviour of electrons and protons in a particle accelerator shows that at the speed of light, all of their electrostatic potential has been transformed into magnetic energy. This shows that the velocity of light relative to it's source is the ratio of it's Electromagnetic Unit of charge ("EMU") and it's Electrostatic Unit of charge ("ESU"). The ratio EMU / ESU is equal to the speed of light "C". Calculating from these details, shows that the total pressure exerted on a single electron by the surrounding ethers is 14.4 dynes which represents a pressure beyond normal comprehension when the minute size of an electron is considered.

16. We now need to consider the role of soft electrons in promoting chemical changes and maintaining life. It has been repeatedly confirmed that magnetic fields have considerable healing properties and will stimulate plant growth. What has not been realised is that it is not the magnetic fields themselves which are responsible for this effect, but it is the soft electrons which they capture and concentrate. One pole of a magnet has beneficial effects for certain ailments, while the opposite pole is not as effective.

One of the most significant properties of soft electrons is their ability to promote chemical changes. A change in a molecule is not likely to take place without lessening the chemical bond or attraction among it's constituent atoms. Soft particles interpenetrating the molecule will bring about this condition by carrying harder electrons in with them, which in turn weakens this bonding by offsetting the positive charge effects of the nucleus. Soft particles tend to camouflage a variety of harder particles. This is a vitally important property because in this manner, other atoms which are going to take part in the chemical change, also have their zonal effects temporarily altered so that they can come into more intimate contact during the reaction. The soft particles tend to act as catalysts for the reacting particles and the soft particles tend to get disintegrated in the process, releasing additional energy which expedites the reaction and allows the normally powerful electrostatic field effects within the atom to return to their original state. The release of the hard electrons contained within the soft particles which disintegrate is the source of much of the heat produced during chemical reactions.

17. The properties of water: water is a universal catalyst because of it's unique ability to collect and concentrate an enormous quantity of soft electrons of all kinds. This is the reason why water has the highest

specific heat of any known substance. The large amount of energy contained in water in the form of soft particles, has been demonstrated by experimenters on many occasions. For example, a number of reports show internal combustion engines running with water as the fuel. No reasonable explanation for this has been given as it appears to be contrary to all the rules of chemistry. However, the disintegration of the more unstable soft particles contained in the water when subjected to compression and ignition inside the engine, accounts for this seeming impossibility.

Water is a unique substance being comprised of two of the most chemically active elements, both of which are gaseous elements. The fact that three oxygen atoms can combine to form ozone, indicates that the oxygen atom is extremely magnetic, indicating that a higher percentage of its orbital electrons are moving in approximately the same plane. This leaves fewer orbital electrons tending to offset the positive charge of the nucleus and other portions of the atom. Consequently, two sides of the oxygen atom possess an inordinately strong overall positive charge. When hydrogen atoms combine with an oxygen atom, the electrons on the side of the hydrogen atoms adjacent to the oxygen atom are brushed aside. This is on the segment of the oxygen atom where most of the electrons of the oxygen atom are orbiting. The normal flow of electrons around the proton of the hydrogen atom is diverted to become a flow which encircles the oxygen atom and the outer periphery of the hydrogen atoms. This results in a powerful magnetic and electrostatic bond between the hydrogen atoms and the oxygen atom. The electron flow around the hydrogen atoms is extremely rapid, resulting in a very high overall positive charge on the hydrogen atoms. As there is a very strong mutual repulsion between the hydrogen atoms, they will line up on opposite sides of the oxygen atom, giving water the structure H-O-H. This molecule has strong and extensive positive zones, so the attraction zone is a considerable distance from the molecules. This is why the specific gravity of water is low, despite the strong positive charge of the molecules.

The great affinity of water for soft electrons is now apparent. The large positive zones between molecules are havens for soft electrons, drawn there by the attenuated, but significant, attraction of the hard electrons captured by the soft electrons. Although soft electrons are large compared to hard electrons, they are still very small compared to an atom. Therefore, the spaces between water molecules can harbour large quantities of soft electrons, without them being bound to the water molecules.

Perhaps the most baffling feature of water is that it expands when it freezes. The high concentration of soft electrons greatly weakens the forces of attraction and repulsion between the molecules. As a result, the average kinetic energy of the molecules at the freezing point are still sufficiently large to allow the molecules to move in and out of the zones of attraction and repulsion, without being confined in the attraction zone. The cooling must continue until the soft electron concentration reaches the stage where the attractive forces become strong enough to confine the molecules to the attractive zone. When this occurs, the water becomes a solid. Since the attractive zone is an inordinate distance from the molecules, the average distance between molecules becomes greater than it was when the water was in a liquid state. At the freezing point, the molecular activity is low enough to permit soft electrons to enter or leave the substance without disintegrating. In order for the water to be transformed from a solid back into a liquid, the same quantity of soft electrons must be injected into it as were removed when it changed from a liquid to a solid.

The melting and freezing temperatures of water vary considerably due to the differing amounts of soft electrons contained in it. Another unusual feature is that in cold weather, hot water pipes have a greater tendency to freeze than cold water pipes do. This is because the heating of the water drove off many of the soft electrons normally contained in the water and due to the low temperature of the surroundings, these soft electrons were not replaced, and as a consequence, freezing to become a solid happens more easily.

One tends to think of colloids as ultra-small particles of solid matter. However, molecules of water can adhere to each other to form aggregates of water molecules, which are effectively, colloids as well. Colloids have strong electrical properties as indicated by the fact that they are not affected by gravity. The field zones around any such colloidal group will be much stronger than that around a single water molecule. Water with a high percentage of such colloidal groups can capture a very large number of soft electrons which are beneficial to health. Abnormal conditions in certain places can favour the formation of water colloids and that can account for the healing properties of water found in some places, such as Lourdes in France.

18. Hard particles can be captured by softer particles and this is deeply involved in a wide range of phenomena, from the transmission of heat and electricity, to the formation of clouds.

Ether particles have zones of attraction and repulsion. Since photons are composed of ether particles, they will in turn, possess zones of attraction and repulsion. In the case of ether particles, these zones will be correspondingly smaller in proportion to the diameter of photons. When protons combine to form electrons or protons, the same zones are present between these particles. However, the zones of attraction are minute when compared to the diameter of the electron or proton, and like particles, seldom if ever get close enough together at sufficiently low velocities for the attractive forces to become effective.

The situation is entirely different when two similar particles composed of photons but with widely differing frequencies, approach each other. Electrostatic attraction or repulsion is considerably lessened because each is associated with ethers which differ considerably from each other. When they are in direct contact with each other, electrostatic repulsion tends to vanish, since there can be little or no bombardments on the sides facing each other. Since each particle associated with ethers is somewhat different, they will tend to interpenetrate. This means that they will be completely within the ether attraction zones of one another. As a result, the harder particle is captured by the softer one. In a similar manner, the captured harder particles will, in turn, capture still harder particles and this process continues until electrons normally associated with electricity are confined. This combination of particles tends to nullify the electrostatic forces which are normally produced by the confined particles, camouflaging the captured harder particles so that their presence is not readily apparent.

The ether particles normally bombarding the hard electrons and protons which produce electrostatic field effects, tend to be diverted from their normal paths by the presence of softer particles or media between the repelling like charges and/or the attracting unlike charges. These interpenetrating softer particles produce an ultra-high concentration of ether particles around the hard particles. The motion of these ether particles is greatly restricted. This offers a barrier to the higher ether particles which normally bombard the hard particles. This has a tendency to slow them down, and any which do collide with the hard particles, do so with considerably less impact than normal, therefore they tend to become electrically neutral and their motion slows to nearly a halt.

Soft particles permeate matter as well as the spaces between matter, yet they do not to any great extent, neutralise the electrostatic field effects of the fundamental particles, because they are more concentrated and their rapid motion tends to prevent capture. However, additional concentrations of soft particles of the right kind, injected into matter, can render the elementary particles within the atom, electrically neutral and the matter becomes what is known as "dematerialised". This conglomeration of soft and hard particles renders the soft particles electrically neutral.

It should be noted that only hard particles or the fundamental particles of the atom, are hollow. All other particles, including photons, do not have this tendency because of the nature of their formation. If the softer particles were hollow, they would be unable to capture harder particles. Hard particles entering a hollow, soft particle, would maintain their charges and force a mutual repulsion. Therefore, they would escape

immediately. Photons, if hollow, would tend to be less stable, and the probability of forming other particles would be lessened.

When a soft particle disintegrates, a chain reaction occurs. The disintegration releases the confined, harder particles. The energy released during the disintegration is generally sufficient to disintegrate the weaker hard particles which it originally captured. This, in turn, results in the disintegration of still harder particles, until the very hard and stable electrons of electricity are released. Highly interesting experiments performed in Poland by two scientists; Howsky and Groot, demonstrated the ability of soft electrons to house and camouflage harder electrons, and to release them under certain conditions. These experiments were also a great confirmation of other principles already mentioned here, especially those involved with levitation.

A small quartz crystal was attached to an oscillator which generated radio frequencies of several kilowatts. This caused the crystal to lose its transparency and increase its volume 800%. The crystal then levitated and carried the oscillator, as well as a 55 pound weight, to a height of two metres above the floor. An account of this was given in an issue of *Science and Invention* magazine and it included a photograph of the levitation.

19. The energies concentrated inside a pyramid have been shown to be extremely beneficial to humans. Soft particle bombardments from outer space and especially from the Sun, concentrate inside the pyramid. Some, passing through the surface of the pyramid are slowed down to such an extent that the Earth's gravitational field, repelling the negative charges, tends to keep them inside until collisions with other particles drives them out.

Most of the particles collected by the pyramid, concentrate along the edges as would be expected, since electricity on any charged body tends to do much the same thing, with concentrations at points and along edges. In fact, pyramid frames have been found to be nearly as effective as the closed pyramid, if, and only if, there is a continuity in the framework and no breaks in any of the joining parts.

The soft electrons collected on a pyramid frame or closed pyramid, soon reach saturation point and continued bombardment causes the excess to drop down inside the pyramid. This, coupled with the gravity-repelling forces, causes a high concentration inside the pyramid. The proportions of the pyramid are apparently a factor in its performance. If the sides are too steep, many of the soft electrons will move along the edges into the ground outside instead of being forced inside the pyramid. If the sides are not steep enough, not many particles will be collected as they strike the material at nearly a right angle which causes only a small reduction in velocity. If they strike at a sharper angle, there is a greater tendency for them to be retained by the material.

If two sides of the base are aligned with magnetic North, it is allegedly more effective. Pyramids can be rendered more potent by lining the interiors of a non-metallic enclosed pyramid, with metal foil such as aluminium or copper. The foil allows a greater quantity of soft electrons to accumulate around the non-metallic outer portion because the soft particles do not pass through the metallic substance as easily, causing a back-up of soft particles. During the process, the foil absorbs large quantities of soft particles before many of them can enter the pyramid. pyramids also radiate soft electrons upwards from the peak.

Many of the soft particles which are stopped briefly on the outside of the pyramid, are repelled upwards by the Earth's gravitational field, and as well, by soft electrons attached to the pyramid. This produces a funnelling effect which ejects soft electrons from the apex of the pyramid. The Earth's gravity accelerates soft particles at a far greater rate than it does ordinary matter as soft particles are associated with ethers which are much closer to those of the gravity-inducing particles than is the case for ordinary matter. After the pyramid becomes saturated, a greater quantity of soft particles than ever, will concentrate inside. The foil will continue to radiate a high concentration of soft particles during the night when the number of particles bombarding the pyramid is considerably reduced.

It is found that pyramids work better during the summer than at any other time of the year. They are also more effective in the lower latitudes because most of the energy concentrated by the pyramid comes from the Sun. There are conflicting opinions as to the effectiveness of pyramids because of this as there is little understanding of the principles involved. For example, those who experiment with pyramids in Canada may claim that they don't work while those in Southern California will contradict them. A pyramid does not increase the flow of soft particles through the area covered by the pyramid as the same concentration flows outside the area. What a pyramid does, is impede the general flow of soft particles and produce a back-up of particles inside and below the pyramid, and consequently, a higher concentration of soft electrons in these regions. The material used in a pyramid is of great importance. This was demonstrated when a wealthy man in the Midwest built a pyramid-shaped house five stories high, which was then covered with gold-plated iron. The phenomena produced were completely unprecedented. For example, ground water was forced to the surface and flooded the first floor. This was because the soft particle concentration inside and below the pyramid was so great that ground water was impregnated with such an abnormal concentration of negative

charges that it was repelled upwards by the Earth's gravity.

Gold atoms have extremely high positive electrostatic field effects, more so than any other atom. This is why gold is the most malleable of all substances. This means that soft electrons will have a greater affinity for gold than for any other metal. As a result, abnormally high concentrations of soft electrons will concentrate around gold. This effect is greatly enhanced when gold is in contact with iron. These dissimilar metals produce an EMF which in turn, causes a flow of electricity or eddy currents resulting in the iron being magnetised. The magnetic field produced, captures additional soft electrons. A higher concentration of soft electrons is created by this combination then could be produced by a similar thickness of gold foil alone. It follows that by far the most effective material that could be used for pyramids is gold-plated sheet iron (galvanised iron should not be used).

With everything else being the same, the greater the size of a pyramid, the better the performance. The reason for this is that the thicker the layer of concentrated soft electrons through which the incoming soft particles must pass, the more they are slowed down when passing. This results in a greater back-up of soft electrons and an increase in the concentration inside the pyramid. Another reason is that a large pyramid has a greater ratio of volume to surface area. Soft electrons are continuously leaking away from the surface of the pyramid, the larger the pyramid, the lower the percentage of soft electrons which is lost. Consequently, very small pyramids are ineffective.

20. Viktor Schauberger of Austria was puzzled by the fact that large mountain trout could remain motionless for as long as they liked in the fastest flowing water in streams. When disturbed, they escape upstream with fantastic speed. He also noticed that water gets charged up through swirling vortex action as it flows around obstructions. As the water is highly agitated, it gives up large quantities of hard and soft electrons to the fish, causing the entire outer surface of the fish to get a high negative charge. This charge repels the outer electrons of the water molecules, totally eliminating drag and as a result, the water exerts almost zero force on the fish. This effect is even more enhanced as the fish moves upstream, much more so than if the fish went downstream. The negative charge also helps the fish jump as the Earth's gravity boosts it upwards.

21. Brown's gas, produced by one form of the electrolysis of water has properties which seem bewildering to most scientists. Using it, allows steel to be welded to a clay brick and the flame is not harmful to human flesh. The flame temperature depends entirely on what it is applied to. It can also reduce nuclear radiation by 96%. The properties of Brown's gas confirm the information above. Water has a very large capacity to store soft electrons in addition to those already present in the structure of water. Brown did not separate water into hydrogen and oxygen. Instead, he added additional soft electrons to the water molecules. These additional charges greatly weakened the cohesive forces between the molecules, converting the water to an unstable gas. All of the properties of Brown's Gas follow naturally from this. Under welding conditions, the vast concentrations of soft electrons supply the release of sufficient quantities of hard electrons to produce the needed heat. In addition, the soft electron concentrations enable iron atoms to partially interpenetrate brick molecules to produce a bond between brick and iron. Also, with the ultra-high concentration of soft electrons, the gas can readily neutralise the positive charges of nuclear radiation.

22. We need to examine the source of the Sun's radiant energy. One thing that all suns seem to have in common is their great size. The astrophysicists speak of white dwarf suns of planetary size or less. It is clear that any claims made by astronomers or astrophysicists concerning celestial determinations, have about the same degree of merit as the other scientific claims which have already been mentioned. There is nothing to justify the existence of a white dwarf. For one thing, due to its allegedly small size and limited gravitational influence, it could only hold very small bodies of asteroid size in orbit around it and those would have to be only a short distance away from it. According to the fallacious theories of orthodox science, a white dwarf consists of atoms with practically all of their electrons stripped away, giving it enormous gravity. It will be shown that astrophysicists have no way of accurately determining the distance or the size of any celestial body.

The larger the body, the greater its mass or volume in proportion to its surface area. This means that as the size increases, it is less probable that the energies produced by the normal activity of the atoms in the body's interior will escape from the surface without a resulting increase of temperature at the surface. The energy radiated from the surface will be in the form of photons and other particles of all types. Below a critical size, the surface area is sufficient to allow all of the radiant energy created in its interior, to escape without an increase in temperature. In fact, such a body will lose heat unless it receives sufficient energy from its surroundings.

As a body increases in size, its surface area becomes increasingly inadequate to allow the radiated energy in its interior to escape without a build up of heat at, and below, the surface. The surface will not radiate the

heat or energy outwards as quickly as it is created in the interior. The rate at which energy is radiated from a surface increases rapidly with a resulting increase in surface temperature. This varies as the fourth power of its absolute temperature. For example, within a certain temperature range, if the temperature is doubled, the rate at which energy is radiated in the form of photons and soft particles, increases by a factor of 16.

The critical size of such a body will depend on its composition. For example, if it contains a high concentration of mildly radioactive substances, this critical size will be less. If the body is hollow, then the dimensions would have to be greater. The red giants, if they are even close to the dimensions claimed, would have to be hollow and have relatively thin shells, otherwise, they would not be red as their surface temperatures would be astronomical.

The actual source of the energy which is finally radiated out into space is the soft particles and photons which are normally radiated by the atoms of the material inside a sun. This is due to the activities of the fundamental particles. Because of the great mass of a sun, an abnormal concentration of these soft particles is always present in the interior. This concentration is greatest near the surface. There is a steady increase in intensity, from the centre toward the outside. This results in a continuous disintegration of a high percentage of those particles near the surface, accompanied by a great increase in temperature, which in turn, results in a greater rate of disintegration, with the release of harder particles which produce the higher temperatures. At the same time, there is an increase in the rate at which the soft particles are created. The temperature will decrease steadily as the centre is approached and any sun will have a relatively cool interior.

The principle that size is the major factor in a celestial body's ability to radiate is confirmed by the behaviour of very large planets such as Jupiter and Saturn. An application of this principle indicates that bodies of such size should start radiating more energy than they receive from outside sources. Recent determinations indicate that Jupiter and Saturn do, in fact, radiate more energy than they seem to receive from the Sun. A probe showed a surprisingly higher temperature in Jupiter's upper atmosphere than was formerly believed to exist.

It now becomes apparent that the conventional theory which states that the radiant energy of the Sun is produced by thermonuclear reactions is complete nonsense. One thing to consider is that if this were the case, the Sun's radiation would be so lethal that no life could exist on any of the planets in the solar system.

Occasionally, throughout the universe, the gradual build up of heat in the interior of suns becomes very much greater, possibly due to the quantity of radioactive elements in the interior caused by transmutation. In such cases, relief valves in the form of sunspots, no longer take care of the excess energy increases and large portions blow apart, releasing astronomical quantities of radiation. After the explosion, the supernova becomes a burnt out body in comparison to its former state. Considering the countless billions of stars within our field of vision, and since only a few supernovas have been observed down through history, it is logical to conclude that it is not the fate of the great majority of stars.

One of the phenomena concerning the Sun, which completely baffles all of the scientists, is that it seems to rotate faster at the equator than it does in the higher latitudes. Sunspots in the vicinity of the equator make a revolution about the Sun in less time than those in the higher latitudes. This is an annoying paradox which can't be pushed aside by these scientists as it is out there for all to observe.

The part of the Sun which we see is a highly fluidic blanket. The region around the Sun's equator could rotate faster if, and only if, a steady external pull is exerted on that region. Otherwise, internal friction would eventually produce a uniform motion. This means that bodies in orbit near the equator and close to the surface, are generating a high concentration of gravity-inducing radiations. It becomes evident that such bodies could not consist of normal matter and are probably composed of atoms and molecules made up of softer particles which are little affected by the Sun's radiation. Such bodies could generate a concentration of gravity radiations considerably out of proportion to their masses. Being constructed of this kind of material, they would be practically invisible.

23. Errors have been made in determining the size and distance of planetary bodies. Charles Fort cited many instances of fiascos which belied astronomers' claims of extreme accuracy in determining stellar and astronomical distances. His revelations did little to enhance their reputations as paragons of integrity.

The principles employed by astronomers in their measurements are essentially the same as those used by surveyors in measuring distances and elevations. However, some surveyors admit that they are unable to determine the height of mountains with any degree of precision and their measurements may be off by as much as 10%. Mr Cater has tested this using an altimeter which was set to zero at sea level and then driven

to the top of a mountain at 42° 30' North latitude, which is supposed to have an elevation of 9,269 feet. The altimeter reading agreed closely with the established elevations of towns along the route ranging from 1,000 to over 4,000 feet. However, at the top of the mountain, the reading was only 8,800 feet. Mr Cater then reset the altimeter to the 9,269 feet attributed to the mountain and retraced his route. At every spot on the return trip, the altimeter consistently indicated elevations more than 400 feet higher than before. Even after several months, the altimeter reading was still more than 400 feet higher than it should be. A similar test was carried out on a mountain with a recorded elevation of 4,078 feet and at the top, the altimeter showed 3,750 feet although it agreed with other established elevations much lower down.

The fact that the altimeter was accurate at all places except the top of the mountain (whose official height was found by triangulation) shows that the methods employed by surveyors and astronomers are far from being accurate. The heights of mountains determined by triangulation will always be considerably more than the true value. There are two factors involved. First, the atmosphere becomes steadily denser as one descends from the top of the mountain. Second, the orgone concentration becomes greater closer to the ground. This means that light rays from a mountain top will be refracted and so appear to be originating from a point well above the top of the mountain. This was also confirmed by a barometric test at the top of Mount Everest which indicates that it is actually 27,500 feet in elevation and not the 29,000 feet previously supposed.

A friend of Mr Cater had his property surveyed to determine the acreage. Afterwards, he checked some of the distances determined by triangulation, using a tape measure, and found significant errors. Refraction of light is clearly throwing triangulation results off. The bulk of refraction effects are caused by orgone concentration. The measurement of mountain elevations taken at different times give different values and this is due to fluctuations in orgone concentrations, which are higher on hot sunny days than on cool cloudy days. Also, they are generally higher during summer months rather than at other times of the year.

The examples above show the unreliability of results obtained by triangulation. Astronomers are faced with additional factors when they try to apply triangulation, such as the Van Allen Radiation Belt, varying concentrations of orgone throughout space, etc. It is not realistic to assume that astronomers can determine planetary and astronomical distances with great precision.

There are several factors which astrophysicists and astronomers have not taken into consideration in their calculations. Perhaps the most important of these is the fact that all electromagnetic radiations including gravity in free space, suffer an attenuation effect which is well above that of the inverse square law. Everywhere in the universe is permeated with soft and hard particles of all kinds. These particles have been radiated by planetary systems for countless ages. This principle is demonstrated by fluctuations in the velocity of light and gravity attenuation.

There is a steady decline in the velocity of light as it travels through space. The reasons for this can be seen from the following considerations. Normal light, or light which has travelled a relatively short distance from its source, immediately resumes its original velocity after passing through a dense medium such as glass or water. As shown earlier, this is due to the close bunching of photons and soft electrons in any given ray. The concentrations of particles in a ray of light tends to decrease after travelling great distances. The farther it travels, the more attenuated the ray becomes. This means that its ability to increase its velocity after passing from a medium of a given density to one of a lesser density, will be reduced. This is, of course, due to the scattering and dissipation of particles within the ray as it encounters the conglomeration of particles moving in random directions throughout space.

Since conglomerations of soft particles permeate all known space, and the distribution is not uniform, it follows that light will experience refraction effects, even when passing through free space. Therefore, even under the best conditions, with observations being made beyond the atmosphere, astronomical observations cannot be made with any degree of accuracy. The difficulty is, of course, compounded when the observations are made inside the atmosphere. It is small wonder that Charles Fort found a wealth of evidence that completely debunked the astronomer's claims of great precision.

The fluctuation in soft particle distribution, along with the refraction effects of the atmosphere, rules out the possibility of averaging out errors by making many observations and applying the mathematical method of least squares. Conventional statistical theory obliterates actual small variations and distorts data by such averaging out processes. The gross errors which crop up despite these methods speak for themselves.

In order to measure the orbital distance of various planets, it was necessary to find the distance of the Earth from the Sun. Originally, this was allegedly found by measuring the angles that two widely separated observation points on the Earth made with the Sun. This is known as the parallax method. The distance to

the Sun was calculated from these angles and the distance between the observation points. The size of the Sun could then be determined, and knowing the orbital period of the Earth around the Sun, the Sun's mass and surface gravity were calculated by applying the false Newtonian concept of gravitation.

More recently, the distance to the Sun, known as the "astronomical unit" was supposedly determined to a high degree of "precision" by measuring the distance of the body Eros by the parallax method when it was closest to the Earth. Knowing the period of Eros' orbit, the distance to the Sun was calculated by the use of Kepler's law which states that "the square of the periods of any two planets are proportional to the cube of their mean distances from the Sun". Since the orbital periods of the planets are known to a reasonable degree of accuracy, most of the other unknowns within the solar system could be calculated by knowledge of the Sun's alleged mass and surface gravity. By now, it should be apparent that it would be a miracle, or at least, one of the strangest coincidences ever, if the actual distances coincided even approximately with the calculated values.

If the Newtonian concept were valid and the planets were held in orbit by only the effects of the Sun's surface gravity, then the orbital periods of the planets would be a reliable means of determining planetary distances. Since it has been proven that the concepts on which these calculations were made are false, it can be safely concluded that the size of the orbits is considerably different from what the astronomers claim. As a result of the dissipation effects of radiation, well beyond that which can be expected from the inverse square law, it follows that planetary distances are very much different from the accepted values.

This excessive attenuation of the gravity effects of the Sun is reflected in the alleged rapid increase of orbital distances of the outer planets. The supposed orbital distances are as follows:

Earth: 1.0 astronomical units.

Mars: 1.52	(difference 0.52)
The asteroids: 2.76	(difference 1.24)
Jupiter: 5.2	(difference 2.44)
Saturn: 9.58	(difference 4.38)
Uranus 19.16	(difference 9.68) and
Neptune 30.24	(difference 11.08)

It does not follow that the longer the orbital period, the greater the planetary distance. For example, within certain limits, the larger and more massive the planet is beyond a certain critical amount, the slower it must move in order to stay in a given orbit. This is because the total gravity effects of the Sun are unable to permeate and affect the entire mass to the extent that they would with a smaller planet. For example, a planet like Saturn could be placed in a stable orbit inside Earth's orbit. Yet it would have to move so slowly in it's orbit that it's orbital period would be much greater than that of Earth. This means that orbital periods are not a reliable gauge for relative orbital distances.

Although planetary and stellar distances are completely unknown as far as astronomers are concerned, and at this time there are no reliable means available of determining them, the diameters of some of the inner planets, including Jupiter and Saturn, can be calculated far more accurately than any of the other values in the realm of astronomy. The orbital distances of the planetary satellites in proportion to planetary diameters as well as their periods can be accurately determined. The determination of these constants is not affected to any significant degree by the dissipating factors of light already mentioned since a planet and it's satellites are about the same distance from the Earth. The main factor which makes it possible to approximate the diameter of any of these planets is the knowledge that they have practically the same surface gravity as Earth does.

If a satellite is very small as is the case with the satellites of Mars, a planetary diameter can be calculated with a high degree of accuracy. In fact, Mars is the only planet in the solar system whose diameter can be reliably determined. Astonishingly, Mars turns out to have a diameter of about 11,300 miles. Using unusual methods, Mr Cater has estimated the diameter of the Sun as over 2,500,000 miles and at a distance of about 277,000 miles from Earth. The Moon diameter at 5,200 miles at an average distance of 578,000 miles, shell thickness 115 miles and surface gravity 98% that of Earth. With a lesser degree of accuracy, the diameter of Venus is assessed at 23,000 miles and Mercury at over 8,000 miles. Jupiter diameter about 230,000 miles and Saturn about 200,000 miles. It is most unlikely that the accepted distances to the stars are even approximately correct.

24. Hard electrons travel through metals more readily than through non-metals. This indicates that they encounter more extensive positive electrostatic fields between atoms and molecules than in non-metals. At the same time, the atoms in metals are usually more mobile or free to move around than is the case with

solid non-metals. This is why the best conductors of electricity are also the best conductors of heat. It is significant that all of the heavier atoms are metals, with the exception of radon which is a gas. This means that such atoms have a higher net positive charge, which causes a stronger mutual repulsion for greater distances on atoms which are not directly connected to each other. This greater extension of the positive zone around such atoms gives them more freedom without breaking the bond which holds them together. The repulsive forces of nearby atoms, increases the mobility of any given atom.

The heavier atoms contain more protons and neutrons bunched together. The outside pressure needed to hold a group of mutually repulsive particles together is independent of the number of particles present.

One might conclude that the heaviest atoms make the best conductors, but this is not the case. Silver, copper and aluminium are the best conductors although their positive field zones are not as extensive, they have less inertia and so are more easily pushed out of the path of a flow of hard electrons. Electrons which flow along conductors are continually colliding with atoms in motion. Therefore, it requires a steady application of electromotive force at the ends of the conductor in order to keep them flowing. The atoms of non-metals are more firmly locked into position and therefore do not have that much of a tendency to move out of the way and this is why they make good insulators. Electrons follow the lines of least resistance and so they tend to move on the surface of the conductor where there is less tendency to collide with atoms.

The rules governing the conductivity of soft electrons are somewhat different from those of hard electrons. Soft electrons are enormous when compared to hard electrons. This can be seen when considering that the average diameter of a particle is directly proportional to its so-called wavelength of the light comprising it (or inversely proportional to the frequency). The ethers associated with atoms and their fundamental particles are much higher in frequency than those associated with soft particles. This means that atoms will offer little resistance to the passage of soft electrons. However, the magnetic fields resulting from thermal agitation of certain atoms and molecules are involved with ethers which are closer in frequency to the ethers directly associated with soft electrons. Consequently, soft electrons will interact with these fields. This explains why metals in general offer greater resistance to the passage of soft electrons than do non-metals.

The ordinary electrical transformer presents an enigma. The secondary of the transformer continues to pour out or eject electrons from a seemingly unlimited source. There is a limited quantity of free electrons in conductors which should be exhausted quite quickly. The standard argument used to account for the source of current is that free electrons in the circuit supply the electrons and are used over and over again. A simple calculation demonstrates that free electrons in conductors are not the source of electricity.

Consider a wire two millimetres in diameter which carries about 10 amps of current. The electron flow is concentrated near the surface of the wire. Since the electricity in a conductor travels at about the speed of light, such a wire 186,000 miles long would have 10 coulombs of electricity distributed over its surface at any instant. The surface area of this wire is 1,840,000 square metres. A parallel plate capacitor having this plate area and a separation of one millimetre, would have a capacity of 0.016 farads. Even with a potential across its plates of 100 volts, it would still only be able to concentrate an equivalent of 1.6 coulombs, and a good part of this electrostatic charge would be due to the displacement of the electrons and protons of the atoms. This voltage is more than enough to concentrate all of the free electrons on the surface of the plates. Similarly, all of the free electrons in the wire example would be involved if the current were maintained with 100 volts. Of course, a wire this long would have too much resistance to carry any appreciable current with 100 volts, but this has nothing to do with the argument just given. As a matter of fact, even 6 volts is far more than enough to produce a current of 10 amps in a wire of 2 mm diameter. Therefore, there aren't enough free electrons in any conductor to supply any appreciable current. This means that the source of electrons in current flow is not coming from free electrons in the conductor. The conclusion is therefore that the hard electrons somehow manage to get through the insulation of the conductor and flow into the wire from outside.

By the law of action and reaction, since a current has inertia, any change in the primary current of a transformer produces a force in the opposite direction in the secondary. This reactive force produces a disturbance of the ethers which produce the voltage or Electromotive Force as a result of increased ether bombardment. The EMF induced in the secondary winding of the transformer, creates a temporary electric void in the wire which draws all kinds of negative charges to the wire. The softer electrons quickly penetrate the insulation and stop at the surface of the wire as they do not travel as readily through a hard electron conductor. These softer electrons absorb most of the electrostatic forces in the insulation which impede the flow of hard electrons, allowing the hard electrons to pass through the insulation and enter the wire.

Electrical charges, composed of photons in nearly all the frequency ranges, permeate all space, since they are continually radiated by stars throughout the universe. They are not easily detected as they are in the

form of conglomerates with the harder particles residing inside the softer ones. The resulting combinations are highly penetrating and it takes something like a voltage induced in a conductor to separate the harder particles from the softer ones. The performance of a transformer can be greatly impaired by completely shielding the secondary winding with a good conductor of electricity such as copper or pure aluminium. This is because the shield tends to impede the flow of soft particles to the secondary. This effect has been verified by experiment.

The terms "EMF" and "voltage" need clarification. The true nature of the phenomena associated with these terms has never been fully understood. All that has been known is that if a conductor is exposed to an EMF, a flow of electricity is produced. Also, voltage is associated with the amount of energy or work which a current is capable of producing. An EMF of a given value can induce a current with a definite voltage. The voltage produced is directly proportional to the EMF impressed on the conductor. Also, the energy of the current is directly proportional to the voltage. The amperage of a current is a measure of the number of electrons passing through each segment of a conductor per second. Since wattage, or the total kinetic energy of this current flow is equal to the amperage multiplied by the voltage, it follows that the amperage is also directly proportional to the energy of the current flow. Therefore, Voltage is a measure of the average kinetic energy of the electrons flowing along the conductor. This in turn, is directly proportional to the square of the average velocity of the electrons. This simple definition of voltage is sadly lacking in all standard textbooks.

An EMF induces an accelerating force on an electron. What is the nature of this force? Basically, there are two methods of producing an EMF. One is by subjecting the conductor to a fluctuating magnetic field, and the other is by exposing the conductor to a difference of potential, such as connecting it between the opposite poles of a battery. In that instance, one battery pole has a negative charge while the opposite pole is positive. The flow of electrons is the result of an electron concentration at one point tending to flow to an area where there is a shortage.

The EMF is produced by direct electrostatic force, which in turn, has a dual nature. There is the tendency for negative charges to be attracted to positive charges, and then there is also the mutual repulsion between negative charges. The voltage attained is directly proportional to the difference of potential existing between the poles of that battery. The difference of potential is equal to the kinetic energy gained by the electrons in moving from one potential to the other.

The EMF produced by a fluctuating magnetic field gives the same results but the process is different. When a conductor is subjected to a fluctuating magnetic field, as with the secondary winding of a transformer, the "free" electrons of the conductor and the outer electrons of the atoms which are not as intimately associated with the atoms, are exposed to differential ether bombardments. It is equivalent to an electrostatic force. When a magnetic field changes, the change does not take place simultaneously throughout that volume of space occupied by the field but it progresses from one portion to another. This creates differential electrostatic ether particle bombardments on electrons within the field. When a conductor cuts magnetic lines as with an AC generator, the electrons are subjected to the same conditions experienced by electrons moving between the poles of a magnet. The accelerating force will be in a direction perpendicular to the direction in which the electrons in the conductor are found to move.

If there were even a small fraction of the free electrons existing in the matter as is believed by our physicists, the negative charge effects of matter would be so great that these bodies would be unable to get close to each other. Much of the charge on capacitors comes from outside the capacitor, as is the case with the flow of electricity in conductors. Actually, free electrons in a conductor are practically non-existent. Hard electrons which are not a part of the atoms are captured by soft particles which permeate matter. The soft particles release hard electrons when subjected to the EMF in a current, or the voltage across the plates of a capacitor.

The current in a straight wire is evenly distributed along the surface where the electron flow encounters the least resistance. The released hard electrons which are directly affected by the EMF, tend to move as a unit partially held together by mutual magnetic attraction. This unit leaves a temporary void behind it which is quickly filled by surrounding hard electrons. Many such groups are started almost simultaneously in a conductor at about the speed of light, although the electrons themselves travel at a much lower velocity. When an EMF is applied to a conductor, something akin to the domino effect is set up in the ethers. This effect travels at the speed of light since it is produced in a similar manner.

That the source of electricity flowing in power lines as well as that produced by generators, comes from soft particles which permeate and surround the area, has been proven during auroral displays. When aurora activity is unusually high, transformers in Canada have been known to burn out and even explode. At the

same time, increase of current flow in power lines has been great enough to trip circuit breakers as far south as Texas. As explained earlier, the concentration of soft electrons in the atmosphere is greatly increased during auroral phenomena. Some areas receive higher concentrations than others at the same latitude.

A loop of wire or a coil offers impedance to alternating current. This property is known as "inductance". Since a single loop of wire has inductance, it follows that the effect can be explained in terms of one loop. Electrons tend to travel along the surface of a conductor as that is the path of least resistance. The major source of this electricity is the high concentration of soft electrons which gather around a conductor and permeate the material. This is due to the relatively high positive charge of the conductor. The greatest concentration is found at the surface and a short distance below the surface. When an EMF is applied to the conductor, free electrons are set in motion. During this process, soft electrons concentrated at and just below the surface tend to disintegrate and release more hard electrons. This is enhanced by the concentration of the soft electrons, which in turn causes an agitation of the soft particles, causing them to become highly unstable.

In a straight wire, most of this disintegration and nearly all of the electron flow takes place below the surface. This condition greatly shortens the mean free path of the electrons and the flow stops immediately after the applied EMF is shut off. Consequently, an alternating current will encounter the same ohmic resistance in a straight wire as will a direct current. However, the situation is different when the conductor is looped.

When an EMF is applied to a loop, the free or released hard electrons below the surface are forced to the outside by centrifugal force, whence a still greater disintegration of soft electrons occurs because the greatest concentration is at the surface. The mean free path of the electrons is greatly increased and the flow continues for a brief period after the EMF travelling in the direction of the current flow ceases. When the EMF continues in the opposite direction as in the case of an alternating current, the force must oppose the momentum of the electron flow still continuing in the opposite direction to that of the new EMF direction. It follows that this impedance will be directly proportional to the number of turns and to the frequency of the AC. It is logical to assume that the deceleration rate of the electron flow is a constant when the EMF is zero. This means that the more quickly that the EMF is applied in the opposite direction, the higher the velocity of flow that will be encountered. It will be a linear function.

It would now seem evident that when the AC is rectified or has been changed to a pulsed DC, the coil will produce an increase in amperage where a straight wire will not. Experiments have confirmed this. It was found that the input amperage of a current was greatly increased after it passed through a coil. The increase was greatest during the initial stage of the applied EMF and soon dropped to a lower value as the concentration of soft electrons around the wire was reduced. It follows that a coil will offer impedance only to an AC current. It follows that pulsed DC has numerous advantages over AC. It can be used to operate transformers as well as AC without suffering impedance.

A steady direct current experiences the same resistance in a coil as it does in a straight wire of the same length. The fluctuating EMF produces extreme agitation of the soft electrons around and inside the wire, resulting in the disintegration of a large percentage of them, and the release of a high concentration of hard electrons. This does not occur during the steady flow of direct current. During the initial application of DC there is a surge of additional current during the build-up of the EMF. When the current is shut off, there will be a momentary surge of current in the opposite direction. The excess of electrons on the surface of the conductor and in the coil will naturally flow towards the void outside the coil and in the opposite direction to which the current was flowing. The concepts just outlined can be applied when building a self-sustaining electric generator.

When an alternating current is applied to a coil, the EMF must overcome the impedance each time the EMF changes direction. The greatest amount of resistance occurs at the beginning of each change and then steadily decreases as the current builds up. The resistance will be at a minimum when the current reaches its maximum. With AC, the EMF changes direction very frequently and so the maximum resistance is encountered for a high percentage of the time.

The flow of electrons in a wire results in a circular magnetic flow around that wire. As mentioned previously, the magnetic effects between electrons moving together tend to cancel each other out. They are drawn together and the resulting ethers encompass the entire group. This also occurs between adjacent wire segments in a coil. The magnetic effects are cancelled out between the segments and a continuous ether flow, encompassing the entire coil, perpendicular to the direction of the current flow, will occur. The solenoid will then behave like a bar magnet with continuous lines of force.

The Earth's atmosphere produces geomagnetism in much the same way that a solenoid produces a

magnetic field. Changes in the atmosphere move along with the Earth in a circular motion. Although there is little motion of the charges relative to the surface, a magnetic field is still created. Magnetic lines, or ethers, flow from the South magnetic region to the North magnetic region as a result of these rotating charges.

25. Despite the fact that our illustrious physicists have managed to develop as highly a destructive device as a nuclear bomb, they still have no concept of the nature and source of the energy released after a detonation. As with all other well-known phenomena, they try to create the illusion that they comprehend and have explained it. As a matter of fact, academic science has not yet supplied satisfactory explanations for any of the simplest and most common everyday phenomena. The energy released by nuclear devices is explained away by stating that it is a conversion of matter into energy in accordance with the false Einstein relation $E = mc^2$. Many readers, especially those steeped in orthodoxy, may be shocked to learn there is no conversion of mass into energy during such a process, nor by any process in which energy is released! The tremendous heat produced in a nuclear blast means that an abnormal quantity of hard electrons were suddenly released by the complete disintegration of all the soft electrons within the area of the explosion. The intense light that accompanies the blast is the result of the photons set free by the disintegration of those soft electrons.

The key to the triggering of the reaction is the neutron. As indicated earlier, a neutron is equivalent to a collapsed hydrogen atom, and yet it is more than this. A hydrogen atom has a strong net positive charge, while the neutron has no net charge. This means that a neutron has collected far more hard electrons than a hydrogen atom. Since a neutron has no charge, it cannot add to the weight of an atom, as is commonly believed.

The concepts introduced in this treatise render all of the old beliefs concerning atomic structure invalid. The weight of an atom is dependent almost entirely on the number of orbital electrons and the number of protons in its nucleus. This will be discussed in more detail later. There is an exception or two to the above rule in the case of certain radioactive elements where the presence of neutrons can actually reduce the weight of an atom. An interchange of excess electrons between protons and neutrons within the nucleus, and thus transformations of protons into neutrons and vice versa, can occur. The neutrons greatly outnumber the protons in the heavier atoms, especially those that are radioactive. During the interchanges between neutrons and protons, excess neutrons disintegrate into protons and hard electrons are ejected from some of the atoms. This results in a transformation of such atoms. Simultaneously, the tremendous interactions between electrons released in this manner as well as from the disintegration of soft electrons in the vicinity cause the higher ethers to be disturbed, ultimately resulting in the production of gamma rays.

The isotope of the more common uranium 238 atom known as U235 is lighter yet it is fissionable and more radioactive than the uranium 238. It is lighter because it supposedly has fewer neutrons than the ordinary uranium atom. The opposite is actually the case. The U235 having more neutrons is more radioactive. The greater interactions within the nucleus result in more hard electrons being released, which reduces the overall positive charge of its nucleus.

There is a continuous interchange of ejected protons transforming back into neutrons and vice versa among the U235 atoms. A similar but less violent interchange takes place among the atoms of U238. A low percentage of the U238 atoms receive more than their share of these interchanges and thus transform into U235 atoms. Most of the hard electrons released which contribute to such interchanges and transformations is the result of the disintegration of soft electrons which permeate the atoms. It follows that the main contributing factor of radioactivity is the presence of soft electrons which house the hard electrons! Therefore, if the soft electron concentration throughout the vicinity of a radioactive substance is reduced, it will lose much of its radioactivity. By now, it has no doubt occurred to the reader, that a Reich cloud-buster pointed at a radioactive material would cause it to lose its radioactivity! This has been proven to be the case. For example, a glowing piece of radium stops radiating when it is placed in front of a cloud-buster.

The source of the energy released during a nuclear blast is now becoming clear. When a fissionable material like U235 or plutonium is bombarded with additional neutrons, the increased activity in the nuclei causes even the most stable soft electrons in the vicinity to disintegrate. A chain reaction of soft electron disintegration in areas well beyond the confines of the fissionable material results. All of the hard electrons and protons originally camouflaged by the soft particles are suddenly released. A tremendous gamma ray production also occurs. Adequate quantities of fissionable materials suddenly brought together can result in a sufficient increase of neutron bombardment of the interior atoms to produce such a result. It is known as the 'critical mass'. The proper fusion of hydrogen atoms can also cause enough soft electron disintegration to produce a similar result. It is now apparent there is no conversion of mass into energy during the process. All of the fundamental particles of the atoms involved remain intact. In fact, there is even more mass following a blast than there was previously, as a result of the additional hard electrons and protons released.

Once again, it is obvious that the Theory of Relativity is in no way concerned.

The monstrous hoax fostered on the public by the Defence Department of the Government, now becomes more than obvious. A Reich cloud-buster can completely deactivate nuclear devices for great distances by drawing away the soft electron concentration from the vicinity of such device. In fact, a cloud-buster can be used for downing fleets of planes carrying nuclear weapons. Combustion is also dependent on soft electron concentrations which of course includes jet engines. Therefore jet engines or missiles cannot function in an area affected by a cloud-buster. The fact that a simple cloud-buster can deactivate a nuclear reactor from a great distance has been proven on numerous occasions. For example, during the time Reich was carrying out intensive experiments with a cloud-buster in Arizona in the early 1950s, a large reactor several hundred miles to the southeast quit functioning. This means that hundreds of billions of tax dollars are being funnelled every year to support a multibillion dollar nuclear industry and other related industries which are rendered obsolete by the device used by Reich.

It is evident that the proper use of the cloud-buster could throw modern warfare back to the stone age. Obviously the drawing of soft particles away from any group would completely enervate each individual and even turn him into a block of frozen flesh. Although a cloud-buster could not completely deactivate a particle beam weapon it could bring down any craft carrying such a device before it could get into position. The potential of the cloud-buster is perhaps greater than even Reich himself realised. Since heat is transferred from one body to another by soft electrons which release harder electrons, the cloud-buster can be used as a highly efficient refrigeration system by drawing soft electrons away from a body. It has been made apparent that this simple device can render present fire fighting techniques obsolete. By use of the cloud-buster in the proper manner, the loss of life and property from fire and storms could become a thing of the past. It also provides dramatic proof of the validity of many of the new concepts introduced in this treatise.

Radioactivity was the subject of a ridiculous, if not amusing, fiasco more than two decades ago when two physicists, Lee and Yang, received the Nobel Prize in 1957. The incident, which was given wide publicity, concerned an error in the parity principle. The parity principle has been defined as "a mathematical concept impossible to define in physical terms". How such a concept could have any bearing on physical reality is not made clear. Generally, anything relating to reality can be defined in terms of reality, which is in conformity with the Law of Cause and Effect.

Incredibly, an experiment was devised to test the validity of this great revelation. It was based on the idea that a radioactive substance should eject more particles in one preferred direction, than in any other. Radioactive cobalt was chosen. It was cooled down to near absolute zero and exposed to a powerful magnetic field produced by a solenoid, in order to align the nuclei. Another physicist, a Dr. Wu, had devoted six months of hard work setting up the experiment. Indeed, it was found that more particles were ejected out of one pole of the solenoid than the other. Which pole was it? Of course, it was the pole out of which the magnetic lines flowed. Naturally, the experiment merely demonstrated that particles tend to travel down magnetic lines of force. The excess of particles that came out of the pole were those barely ejected from the atom. They had such a low initial velocity that, regardless of what direction they happened to be travelling initially, the magnetic field would dictate their final direction of travel.

Lee and Yang were accorded every scientific honour, including the Nobel Prize, as a result of this experiment. Instead of giving them the Nobel Prize, the awarding of an Oscar would have been more appropriate. Accompanying the extensive publicity given this comedy act was a photo appearing in a prominent magazine showing one of the recipients pointing to a grotesque mathematical equation containing over 100 terms! He was allegedly explaining the reasoning behind their great revelation.

The great nuclear scare scam should rate as the biggest lie of the century. This fabrication is so colossal even Mr Cater is somewhat embarrassed to admit he was also taken in by it, as everyone else was, except those directly involved in the conspiracy but Mr Cater never questioned it as he had other universally accepted beliefs. The long-hidden truth is this: radiation from radioactive substances is relatively harmless! One can actually swim in water from so-called high level nuclear waste, drink the water and actually thrive on it. Also one can handle pure U235 and even plutonium (the fuel for A-bombs) with bare hands all day long, and suffer no ill effects. Of course excessive exposure to this radiation can be inimical, as can occur from any other type of radiation such as sunlight. The effects, however, are immediate and not long-lasting if the source of the trouble is removed. The popular belief that mutations can result from this radiation that effects future generations, is complete nonsense. A study of the effects on the victims of Hiroshima and Nagasaki bear this out. The only mutations are immediate damage to cells and subsequent malfunctions from ultra-high concentrations.

For the above revelations we are indebted to a courageous and dedicated individual who worked for 35 years in the nuclear industry. He was intimately involved in every aspect of the production of nuclear fuels and the building of reactors. He is Galen Windsor, of Richland, Washington. The so-called lethal nuclear radiations are relatively harmless, with very limited penetration. In 1987, Galen had already lectured in 77 different cities over a two-year period. His credentials are impressive. He has worked in every major reactor decommissioning project in America. He was involved in the analytical process inventory control, which was responsible for measuring and controlling the nuclear fuel inventory for these projects. He has few peers in this field and all of them agree with him but are afraid to speak out. He is one of the world's greatest authorities of nuclear radiation measurement.

He and others did plutonium processing using their bare hands until radiation monitors were installed at every reactor. Rules were laid down as to the amount of exposure to radiation that must not be exceeded. If the rules were not followed, the worker disappeared and was never seen again by anyone. The reason is obvious. If word leaked out that radioactive materials below critical mass were harmless, then there would be widespread pilfering of such products. The lie that radioactive materials can be handled only with extreme safety precautions must be maintained at all costs. The high-level disposal act of 1982 calls for the permanent disposal of the so-called high level waste 3,000 feet underground. This high level waste consists of reusable uranium fuel and contains useful metal isotopes. Every ton of it is worth about 10 million US dollars.

Enough has been collected to pay off the National Debt. Portland General Electric owns the Trojan reactor and had a storage basin problem. Windsor offered to take all of their spent fuel off their hands. He would ship it, store it, and do everything that needed to be done at no expense to them, if they would give it to him. They told him "Go to Hell, Galen Windsor - we value it more than plutonium or gold. We are going to play the plutonium future ourselves".

Windsor was taken to California in 1965 to help design and build a nuclear fuel reprocessing plant. After it was built in 1973, a presidential order was issued which said the plant was not to be run. At that time, they had 170 metric tons of spent fuel stored in the basin. Also, the maximum allowed exposure was further reduced by a factor of 10. This was the beginning of Windsor's rebellion against "The Establishment". He began swimming in a 660,000 gallon pool containing the spent fuel. The radioactive materials it contained were enough to maintain a water temperature of 100° F and the water would glow with a bluish light in the dark. He discovered that the tank provided good drinking water.

Windsor was also asked about what was in the burial sites of so-called low-level nuclear waste. The answer was that there are no nuclear wastes, only materials produced in a reactor to be recovered and used beneficially. Low-level waste is an excuse for a Federally-mandated non-inspectable disposal system, so that organised crime can get rid of any evidence they want, and that it can never be dug up again. Also, so that no one finds out whose bodies are in those drums. This is what is contained in barrels that are dropped in the ocean.

Windsor also stated, (and he was in a position to know), that in 1947 the United States sent to the USSR all the necessary materials and technology to build A-bombs! This was under the approval of President Truman. In 1949, they exploded their first A-bomb. Later, the Rosenbergs were executed for allegedly turning over nuclear "secrets" to the Russians.

According to Windsor, by 1975 large reactors no longer had a future. They are being phased out. The notorious Three-Mile Island incident was no accident. It did no damage and no one was harmed. But, it did impress upon the public the alleged danger of reactors. Windsor advocated the use of many small reactors systematically distributed. They could be not only used for producing adequate quantities of electricity, but for obviating refrigeration of packaged foods. When briefly exposed to the radiation from such reactors they will keep indefinitely. A Federal energy cartel is the reason that the effective use of many smaller reactors is not implemented. They control the amount of electricity, the availability and the price. Windsor stated that no reactors have been built correctly. In any event, reactors can in no way, match the use of self-sustaining electric generators for electricity, but their use in preserving food is intriguing.

From the above, it becomes obvious that recent publicity concerning the danger of radon gas in homes is another monstrous hoax! It could be mixed with oxygen in sizeable quantities and breathed for long periods without damage.

The question now arising is why are the radiations from radioactive sources relatively harmless? Three types of radiation emanate from them: alpha, beta and gamma rays. Alpha rays consist of helium nuclei or a small group of protons, neutrons and electrons. The number of neutrons and protons are still unknown

despite the vaunted claims of nuclear physicists. Since they are totally ignorant as to their true nature, the nature of gravity and soft particle physics, they have no means of determining such values. Beta particles are the hard electrons of ordinary electricity, and gamma rays are negative charges comprised of ether particles in the same range as that of hard electrons. As such, they have no more penetrating ability than a stream of hard electrons and are no more damaging than the hard electrons when they do penetrate. Since they are comprised of the same ethers as atoms and molecules, it follows that they will not penetrate matter as readily as softer particles. This leaves the alpha rays. It has already been shown that positive charges are inimical to living tissues since they tend to absorb the negative charges living organisms require. However, alpha particles also have little penetrating ability for the same reasons as given above, and quickly absorb electrons to become harmless helium gas. Windsor gave demonstrations of such facts at his lectures by use of a Geiger counter.

The capture of large quantities of alpha particles by high concentrations of orgone energy is another matter. Reich termed it deadly orgone energy. The orgone enters the body and releases alpha particles throughout vital organs and produces what is known as radiation sickness. Reich and his assistants had this experience. When the source of the trouble was removed they quickly recovered. Occasionally, deadly orgone can remain in the body and at later periods, release the positive charges at various times, thus causing severe after-effects. This problem can be alleviated by treatments inside orgone accumulators or pyramids after being exposed to the deadly orgone. This is what Reich and his helpers did.

Galen Windsor also stated that the bomb dropped on Hiroshima contained 20 pounds of U235. The one exploded over Nagasaki had 2.5 kilograms or about 5 pounds of plutonium. These values were jealously guarded secrets for a long time. Windsor is likely the first one who has dared reveal it to the public. The author was acquainted with the late Stanislaw Ulam, a mathematician who had calculated the critical mass of these elements for bombs while working on the Manhattan project. It was a deep, dark secret and he would have parted with his life before he would reveal anything so sacred. The degree of the hang-up officialdom has on secrecy is of a magnitude difficult to comprehend, and the steps they have taken to insure it is even more mind-boggling. It is so infantile and childish that there are no words in the English language to describe it adequately.

Radioactive substances such as plutonium, produce their own heat and the larger the mass, the higher the temperature of the mass. This follows identically, the same principle by which the Sun generates its energy or the ratio between mass and surface area. The essential difference is that plutonium can do in a few cubic inches what ordinary matter does in a ball 2,500,000 miles in diameter!

Interestingly enough, Windsor looks about 30 years younger than his chronological age would indicate. He also stated he always sustained a healthy tan from his work with radioactive substances. It is significant that Reich and his assistant had a similar experience in their work with orgone energy. It is clear Windsor and Reich were exposed to the same energies, high concentrations of soft electrons. The constant exposure to high orgone concentrations during his working hours is what has kept Galen Windsor young. Of course the high orgone concentrations was produced by soft electrons clustering around the radioactive substances which produced a constant flow of positive charges.

You may wonder why Windsor and certain others could handle radioactive substances with impunity while others have either died or suffered from serious physical problems after being exposed to the radiation. As mentioned earlier, radioactive materials radiate highly positively charged particles which are extremely inimical. Some are absorbed by soft electrons and become DOR (deadly orgone energy). They can enter the body and remain for long periods before disintegrating and releasing the deadly particles. These particles are very sluggish when compared to negative particles including soft electrons.

The victims of radioactive fallout are not exposed for any significant period to high concentrations of positive charges. Also, the area of exposure is very large; consequently, the Coanda effect does not come into play and there is no rush of orgone energy to alleviate the situation as was the case with Windsor when he was directly exposed to ultra high concentrations of radioactive materials. Any victim of radioactive contamination can be cured by being exposed to high concentrations of orgone for extended periods as was Reich and his assistants after experiencing radioactive sickness. They had received a heavy dose of DOR as mentioned earlier. Being exposed to high concentrations of radioactivity is equivalent to being placed in an orgone accumulator.

This is only a summary of part of Mr Cater's book which has 586 pages. A number of topics are not even mentioned here. Mr Cater also speaks of:

Superconductivity.
The properties of Helium at low temperatures.
Mystery spots on Earth, including the famous Oregon Vortex.
Gravitational anomalies.
The origin of the Van Allen Radiation Belt.
The research of William Reich.
Orgone energy.
The Oranur Experiment.
The Reich Cloud Buster (which is also a weapon of major power).
Atmospheric phenomena.
Three practical Free-Energy devices.
The great potential of crystals in the obtaining of Free-Energy.
The work of Nikola Tesla with Free-Energy.
The Searle Effect and many other topics.

If you wish to buy a copy of his book, it is supposedly available at these two outlets:

<http://www.healthresearchbooks.com/> or in the UK from <http://www.amazon.co.uk>. I have ordered and paid for a copy of this book on three occasions and every time, the supplier claimed to be unable to supply what was advertised for sale

So, having absorbed some of what Mr Cater has to say, do you feel that you have been treated fairly, and that the true scientific details were presented to you as part of your general education?

Patrick Kelly

Chapter 12: Basic Electronics

Introduction

This document is not an in-depth presentation of the subject of electronics. Instead, it is intended to give you sufficient (empirical) knowledge of the subject to be able to understand, design and build simple circuits such as the control circuits used with the 'Free Energy' devices described in the later parts of this eBook.

Disclaimer

This material is provided for information purposes only. Should you decide to attempt construction of some device based on information presented here and injure yourself or any other person, I am not liable in any way. To clarify this; should you construct something in a heavy box and drop it on your toe, I am not liable for any injury you may sustain (you should learn to be more careful). If you attempt to construct some electronic circuit and burn yourself with the soldering iron, I am not liable. Also, I strongly recommend that unless you are expert in electronics, you do not construct any device using, or producing more than 30 Volts - high voltage circuits are extremely dangerous and should be avoided until you gain experience or can obtain the help and supervision of a person experienced in constructing high voltage circuits.

Voltage.

Voltage is the key to understanding electronics. Without voltage, nothing happens in electronics. What is it? Nobody knows. We know how to generate it. We know what it does. We know how to measure it, but nobody knows what it actually is.

It is also called "Electro Motive Force" or "EMF" which is no help whatsoever in knowing *what* it is. That, is roughly equivalent to saying "the thing that pushes is the thing that pushes" - very true but absolutely no help whatsoever. OK, having admitted that we really don't know *what* it is, we can start to say the things we do know about it:

A new battery has a voltage between its terminals. This voltage is said to cause a current to flow through any complete electrical circuit placed across it. The current flowing through the circuit can cause various things to happen such as creating light, creating sound, creating heat, creating magnetism, creating movement, creating sparks, etc., etc.

By using the current caused by a voltage, a device called a 'Voltmeter' can indicate how big the voltage is. The bigger the voltage, the bigger the current and the bigger the display on the voltmeter. The voltmeter can have a numerical display where you read the voltage directly from the display, or it can be an 'analogue' voltmeter where the voltage is shown by the position of a needle on a scale. The size of the voltage is stated in 'Volts' which is a unit of measurement named after the man Volta who introduced voltage to the world (it was always there, we just did not know about it).

Voltages add up if they are connected the same way round, i.e. with the + terminals all facing the same way:

The physical size of the battery usually determines the length of time it can supply any given current - the bigger the battery, the longer it can provide any given current. A battery is constructed from a number of 'cells'. The number of cells in the battery controls the voltage of the battery. For example, an 'AA' size battery (what used to be called a 'penlight' battery) has a single 'cell' and so produces 1.5 Volts when new. The very much larger and heavier 'D' battery also has just one cell and so it also produces 1.5 Volts when new. The difference (apart from the higher cost of the 'D' cell) is that the larger cell can provide a much higher current if both batteries are discharged over the same period of time.

There are several different types of battery construction. A rechargeable NiCad battery has a single cell but its construction method means that it produces about 1.35 Volts when fully charged. In passing, NiCad batteries have a 'memory' characteristic which means that if they are recharged before they are fully discharged, then the next time they are discharged they run out of power at the voltage level it had when the last charging was started. Consequently, it is a good idea to fully discharge a NiCad battery before charging it again.

Car and motorcycle batteries are described as Lead/Acid batteries. This type of construction is not very convenient being large, heavy and potentially corrosive. The big advantages are the ability to provide very high currents and giving 2.0 Volts per cell. These batteries are normally produced as 6 Volt or 12 Volt units. The Amp-Hours for lead/acid car batteries is usually quoted for a 20 hour discharge period, so a fully charged, new, 20 Ahr battery can provide 1 Amp for 20 hours of continuous use. That battery loaded to give 5 Amps, will **not** provide that current for 4 hours but might only last 2 hours, or perhaps a little better. The manufacturers literature should give an indication of the performance, but if it is important, run your own test to see how the battery actually works in practice.

"Mains units" are known in the electronics world as "Power Supply Units" or "PSUs" for short. These convert the mains voltage (220 Volts in UK, 110 Volts in USA) to some convenient low voltage; 12 Volts, 9 Volts, 6 Volts, or whatever is needed. A mains unit can provide several different voltages simultaneously.

Resistance.

Being familiar with Voltage and Resistance is the key to understanding electronic circuitry. Resistance is a measure of how difficult it is for current to flow through something. Some materials such as glass, ceramics, wood and most plastics do not easily carry a current and so are considered to be 'insulators'. That is why you will see power lines hung from their pylons by a series of ceramic discs. Current flows easily through metals, especially along the surface of the metal, so cables are made from metal wires surrounded by a layer of plastic insulation. The higher grade cables have wire cores made up of many small-diameter strands as this increases the surface area of the metal for any given cross-sectional area of the metal core (it also makes the cable more flexible, and generally, more expensive).

There is a very important, third group of materials, silicon and germanium in particular, which fall between conductors and insulators. Not surprisingly, these are called 'semi-conductors' and the amount of current they can carry depends on the electrical conditions in which they are placed. Much, much more about this later on.

While a metal wire carries current very well, it is not perfect at the job and so has some 'resistance' to current flowing through it. The thicker the wire, the lower the resistance. The shorter the wire, the lower the resistance. The first researchers used this characteristic to control the way circuits operated. Sometimes, as higher resistances were needed, the researcher used to need long lengths of wire which would get tangled up. To control the wire, a board with nails along each side was used and the wire wound backwards and forwards across the board like this:

When drawing a circuit diagram, the researcher would sketch the wire on the board giving a zig-zag line which is still used today to represent a 'resistor' although different methods of construction are now used. An alternative symbol for a resistor is a plain rectangle as shown above.

If a resistor is connected across a battery, a circuit is formed and a current flows around the circuit. The current cannot be seen but that does not mean that it is not there. Current is measured in 'Amps' and the instrument used to display it is an 'ammeter'. If we place an ammeter in the circuit, it will show the current flowing around the circuit. In passing, the ammeter itself, has a small resistance and so putting it in the circuit does reduce the current flow around the circuit very slightly. Also shown is a bulb. If the current flowing around the circuit is sufficiently high and the bulb chosen correctly, then the bulb will light up, showing that current is flowing, while the ammeter will indicate exactly how much current is flowing:

Shown on the right, is the way that this circuit would be shown by an electronics expert (the 'Resistor', 'Ammeter' and 'Lamp' labels would almost certainly not be shown). There are several different styles of drawing circuit diagrams, but they are the same in the basic essentials. One important common feature is that unless there is some very unusual and powerful reason not to do so, every standard style circuit diagram will have the positive voltage line horizontally at the top of the diagram and the negative as a horizontal line at the bottom. These are often referred to as the positive and negative 'rails'. Where possible, the circuit is drawn so that its operation takes place from left to right, i.e. the first action taken by the circuit is on the left and the last action is placed on the right.

Resistors are manufactured in several sizes and varieties. They come in 'fixed' and 'variable' versions. The most commonly used are the 'fixed' carbon 'E12' range. This is a range of values which has 12 resistor values which repeat: 10, 12, 15, 18, 22, 27, 33, 39, 47, 56, 68, 82 and then: 100, 120, 150, 180, 220, 270, 330, 390, 470, 560, 680, 820 and then: 1000, 1200, 1500, 1800, 2200, 2700, 3300, 3900, 4700, 5600, 6800, 8200, etc. etc. Nowadays, circuits often carry very little power and so the resistors can, and are, made in very small physical sizes. The higher the resistance value of a resistor, the less current will flow through it when a voltage is placed across it. As it can be difficult to see printing on small resistors clustered together on a circuit board and surrounded by other larger components, the resistor values are not written on the resistors, instead, the resistors are colour-coded. The unit of measurement for resistors is the 'ohm' which has a very small size. Most resistors which you encounter will be in the range 100 ohms to 1,000,000 ohms. The higher the resistance of any resistor, the smaller the current which will flow through it.

The colour code used on resistors is:

- 0 Black
- 1 Brown
- 2 Red
- 3 Orange
- 4 Yellow
- 5 Green
- 6 Blue
- 7 Purple (Violet if your colour vision is very good)
- 8 Grey
- 9 White

Each resistor has typically, three colour bands to indicate its value. The first two bands are the numbers and the third band is the number of noughts:

Green: 5
 Blue: 6
 Red: 2 noughts
 Value: 5,600 ohms or 5.6K or 5K6

Yellow: 4
 Purple: 7
 Green: 5 noughts
 Value: 4,700,000 ohms or 4.7M or 4M7

The colour bands are read from left to right and the first band is close to one end of the body of the resistor. There is often a fourth band which indicates the manufacturing tolerance: you can ignore that band.

Examples:

Red, Red, Red: 2 2 00 ohms or 2K2

Yellow, Purple, Orange: 4 7 000 ohms or 47K

Brown, Black, Brown: 1 0 0 ohms or 100R

Orange, Orange, Orange: 3 3 000 ohms or 33K

Brown, Green, Red: 1 5 00 ohms or 1K5

Brown, Green, Black: 1 5 no noughts, or 15 ohms

Blue, Grey, Orange: 6 8 000 ohms or 68K

Brown, Green, Green: 1 5 00000 ohms or 1,500,000 ohms or 1M5

Yellow, Purple, Brown: 4 7 0 ohms

As there are only 12 standard resistor values per decade, there are only 12 sets of the first two colour bands:

10: Brown/Black,

12: Brown/Red,

15: Brown/Green,

18: Brown/Grey

22: Red/Red,

27: Red/Purple

33: Orange/Orange,

39: Orange/White

47: Yellow/Purple

56: Green/Blue

68: Blue/Grey

82: Grey/Red

	10		100		1K
	12		120		1.2K
	15		150		1.5K
	18		180		1.8K
	22		220		2.2K
	27		270		2.7K
	33		330		3.3K
	39		390		3.9K
	47		470		4.7K
	56		560		5.6K
	68		680		6.8K
	82		820		8.2K

	10K		100K		1M
	12K		120K		1.2M
	15K		150K		1.5M
	18K		180K		1.8M
	22K		220K		2.2M
	27K		270K		2.7M
	33K		330K		3.3M
	39K		390K		3.9M
	47K		470K		4.7M
	56K		560K		5.6M
	68K		680K		6.8M
	82K		820K		8.2M

Black = 0 or None, Brown = 1, Red = 2, Orange = 3, Yellow = 4, Green = 5, Blue = 6, Purple = 7, Grey = 8, White = 9

The details above give you all the basic information on resistor colour codes but there are a few additional refinements. There is an extra colour band further down the body of the resistor as shown here:

This extra band is used to indicate the manufacturing tolerance of the construction of the resistor. Resistor values are never exact and this rarely has any significant effect on their use in circuits. If some circuit needs very accurate resistor values in it, then buy several resistors of the same nominal value and use an ohm-meter to measure that actual value of each particular resistor and if none are perfect, then use two or more resistors to give the exact value wanted.

The tolerance band has the following codes:

Silver is $\pm 10\%$ (i.e. a 10K resistor of this type should be between 9K and 11K)
Gold $\pm 5\%$ (i.e. a 10K resistor of this type should be between 9.5K and 10.5K)
Red $\pm 2\%$ (i.e. a 10K resistor of this type should be between 9.8K and 10.2K)
Brown $\pm 1\%$ (i.e. a 10K resistor of this type should be between 9.9K and 10.1K)
Green $\pm 0.5\%$ (i.e. a 10K resistor of this type should be between 9.95K and 10.05K)
Blue $\pm 0.25\%$ (i.e. a 10K resistor of this type should be between 9.975K and 10.025K)
Purple $\pm 0.1\%$ (i.e. a 10K resistor of this type should be between 9.99K and 10.01K)

This type of resistor in the 10% and 5% ranges are the most common as they are the cheapest to buy and so tend to be the most popular. Recently, however, two additions to the coding have been introduced in order to allow for very high specification resistors which the average constructor may never come across. Each of these additions involves one additional colour band. The first additional colour band allows an extra digit in the resistor value, and looks like this:

As before, the colour coding is exactly the same, with the fourth colour band specifying the number of zeros after the digits indicated by the colour bands in front of it. So, in the example shown above, the first band being Red indicates a "2". The second colour band being Purple indicates a "7". The third colour band being Green indicates a "5" and the fourth colour band being Red indicates "2 zeros", so putting those together it produces the value of 27,500 ohms, which can also be written as 27.5 K or more briefly as 27K5.

Another example of this is:

The fourth colour band coding has also been extended to include two other colours:

Gold: meaning "no zeros and divided by 10" so if the band in the example above had been gold, then the value would be 56.4 ohms.

Silver: meaning "no zeros and divided by 100" and if the example band had been silver then the value would have been 5.64 ohms.

So, for example, if the resistor had a fourth colour band which was silver, then the value would be:

Finally, for very high-quality applications (typically military applications), there can be a sixth colour band positioned outside the tolerance band, and that final colour band states how much the resistance value can be expected to alter with changes in temperature. This is not something which is likely to be of any interest to you, but the codes for that final colour band are:

- Brown: 0.01% of the resistor value for each degree Centigrade change in temperature.
- Red: 0.005% of the resistor value for each degree Centigrade change in temperature.
- Yellow: 0.0025% of the resistor value for each degree Centigrade change in temperature.
- Orange: 0.0015% of the resistor value for each degree Centigrade change in temperature.

To put this in context, the worst of these represents a change of 1% in the resistor value when moving from the temperature of ice to the temperature of boiling water. Is this something which you really care about? I don't.

Leaving the details of identifying individual resistors, we now come to the interesting part: what happens when there are several resistors in a circuit. The important thing is to keep track of the voltages generated within the circuit. These define the currents flowing, the power used and the way in which the circuit will respond to external events. Take this circuit:

What is the voltage at point 'A'? If you feel like saying "Who cares?" then the answer is "you" if you want to understand how circuits work, because the voltage at point 'A' is vital. For the moment, ignore the effect of the voltmeter used to measure the voltage.

If R1 has the same resistance as R2, then the voltage at 'A' is half the battery voltage, i.e. 4.5 Volts. Half the battery voltage is dropped across R1 and half across R2. It does not matter what the actual resistance of R1 or R2 is, as long as they have exactly the same resistance. The higher the resistance, the less current flows, the longer the battery lasts and the more difficult it is to measure the voltage accurately.

There is no need to do any calculations to determine the voltage at point "A" as it is the ratio of the resistor values which determines the voltage. If you really want to, you can calculate the voltage although it is not necessary. The method for doing this will be shown you shortly. For example, if R1 and R2 each have a value of 50 ohms, then the current flowing through them will be 9 volts / 100 ohms = 0.09 Amps (or 90 milliamps). The voltage drop across R1 will be 50 ohms = Volts / 0.09 amps or Volts = 4.5 volts. Exactly the same calculation shows that the voltage across R2 is exactly 4.5 volts as well. However, the point to be stressed here is that it is the **ratio** of R1 to R2 which controls the voltage at point "A".

If R1 has half as much resistance as R2, then half as much voltage is dropped across it as is dropped across R2, i.e. 3 Volts is dropped across R1, giving point 'A' a voltage of 6 Volts and that is what the voltmeter will show. Again, it does not matter what the actual value of R1 is in ohms, so long as R2 has exactly twice the resistance (shown by a higher number on the resistor).

If R1 has twice as much resistance as R2, then twice as much voltage is dropped across it as is dropped across R2, i.e. 6 Volts is dropped across R1, giving point 'A' a voltage of 3 Volts. Here are some examples with different resistors:

The same division of the supply voltage can be produced by positioning the slider of a variable resistor at different points by rotating the shaft of the device:

This determination of the voltage levels is the key factor to understanding electronic circuitry. The voltage levels control what currents flow and how every circuit will perform, so it is essential to understand what is happening. Stick with this section until you understand it, and if necessary, ask questions about what you find difficult.

First, please understand that a good battery is an unlimited source of voltage and that voltage does not get “used up” when a resistor or whatever is connected across it:

There can be some difficulty in understanding the “0-volt” connection in a circuit. All this means is that it is the return line for current flowing from the battery. Most conventional circuits are connected to both sides of the battery and that allows a current to flow around a closed “circuit” from one terminal of the battery to the other terminal.

It is normal practice to draw a circuit diagram so that the Plus terminal of the battery is at the top and the minus terminal is at the bottom. Many circuit diagrams show the negative line at the bottom connected to the ground or an “earth” connection, which is literally a metal rod driven into the ground to make a good electrical connection to the ground. This is done because the Earth is literally a vast reservoir of negative electricity. However, in reality, most circuits are not connected directly to the Earth in any way. The standard circuit diagram can be visualised as being like a graph of voltage, the higher up the diagram, the higher the voltage.

Anyway, when there is a circuit connected across the battery, the negative or “0V” line just indicates the return path to the battery for the current flow:

This principle applies immediately to the following circuit:

Here we encounter two new components. The first is 'VR1' which is a variable resistor. This device is a resistor which has a slider which can be moved from one end of the resistor to the other. In the circuit above, the variable resistor is connected across the 9 Volt battery so the top of the resistor is at +9 Volts (relative to the battery Minus terminal) and the bottom is at 0 Volts. The voltage on the slider can be adjusted from 0 Volts to 9 Volts by moving it along the resistor by turning the shaft of the component (which normally has a knob attached to it).

The second new device is 'TR1' a transistor. This semiconductor has three connections: a **C**ollector, a **B**ase and an **E**mitter. If the voltage on the base is below 0.7 volts, then the transistor is said to be "OFF" and in that state it has a very high resistance between the collector and the emitter, much higher than the resistance of resistor "R2". The voltage dividing mechanism just discussed means that the voltage at the collector will therefore, be very near to 9 Volts - caused by the **ratio** of the transistor's Collector/Emitter resistance compared to the resistor "R2".

If the voltage on the base of the transistor is raised to 0.7 volts by moving the slider of the variable resistor slowly upwards, then this will feed a small current to the base which then flows out through the emitter, switching the transistor ON causing the resistance between the collector and the emitter to drop instantly to a very low value, much, much lower than the resistance of resistor 'R2'. This means that the voltage at the collector will be very close to 0 Volts. The transistor can therefore be switched on and off just by rotating the shaft of the variable resistor:

If a bulb is used instead of R2, then it will light when the transistor switches on. If a relay or opto-isolator is used, then a second circuit can be operated:

If a buzzer is substituted for R2, then an audible warning will be sounded when the transistor switches on. If a light-dependent resistor is substituted for VR1, then the transistor will switch on when the light level increases or decreases, depending on how the sensor is connected. If a thermistor is used instead of VR1, then the transistor can be switched on by a rise or fall in temperature. The same goes for sound, windspeed, water speed, vibration level, etc. etc. - more of this later.

We need to examine the resistor circuit in more detail:

We need to be able to calculate what current is flowing around the circuit. If the circuit contains only resistors, then this can be done using "Ohm's Law" which states that "Resistance equals Voltage divided by Current" or, if you prefer:

Ohm's Law (resistive Circuits only).

"Ohms = Volts / Amps" which indicates the units of measurement.

In the circuit above, if the voltage is 9 Volts and the resistor is 100 ohms, then by using Ohm's Law we can calculate the current flowing around the circuit as $100 \text{ Ohms} = 9 \text{ Volts} / \text{Amps}$, or $\text{Amps} = 9 / 100$ which equals 0.09 Amps. To avoid decimal places, the unit of 1 milliamp is used. There are 1000 milliamps in 1 Amp. The

current just calculated would commonly be expressed as 90 milliamps which is written as 90 mA.

In the circuit above, if the voltage is 9 Volts and the resistor is 330 ohms, then by using Ohm's Law we can calculate the current flowing around the circuit as $330 = 9 / \text{Amps}$. Multiplying both sides of the equation by "Amps" gives: $\text{Amps} \times 330 \text{ ohms} = 9 \text{ volts}$. Dividing both sides of the equation by 330 gives: $\text{Amps} = 9 \text{ volts} / 330 \text{ ohms}$ which works out as 0.027 Amps, written as 27 mA.

Using Ohm's Law we can calculate what resistor to use to give any required current flow. If the voltage is 12 Volts and the required current is 250 mA then as $\text{Ohms} = \text{Volts} / \text{Amps}$, the resistor needed is given by: $\text{Ohms} = 12 / 0.25 \text{ Amps}$ which equals 48 ohms. The closest standard resistor is 47 ohms (Yellow / Purple / Black).

The final thing to do is to check the wattage of the resistor to make sure that the resistor will not burn out when connected in the proposed circuit. The power calculation is given by:

Watts = Volts x Amps. In the last example, this gives $\text{Watts} = 12 \times 0.25$, which is 3 Watts. This is much larger than most resistors used in circuitry nowadays.

Taking the earlier example, $\text{Watts} = \text{Volts} \times \text{Amps}$, so $\text{Watts} = 9 \times 0.027$ which gives 0.234 Watts. Again, to avoid decimals, a unit of 1 milliwatt is used, where 1000 milliwatts = 1 Watt. So instead of writing 0.234 Watts, it is common to write it as 234 mW.

This method of working out voltages, resistances and wattages applies to any circuit, no matter how awkward they may appear. For example, take the following circuit containing five resistors:

As the current flowing through resistor 'R1' has then to pass through resistor 'R2', they are said to be 'in series' and their resistances are added together when calculating current flows. In the example above, both R1 and R2 are 1K resistors, so together they have a resistance to current flow of 2K (that is, 2,000 ohms).

If two, or more, resistors are connected across each other as shown on the right hand side of the diagram above, they are said to be 'in parallel' and their resistances combine differently. If you want to work out the equation above, for yourself, then choose a voltage across R_t , use Ohm's Law to work out the current through R_a and the current through R_b . Add the currents together (as they are both being drawn from the voltage source) and use Ohm's Law again to work out the value of R_t to confirm that the $1/R_t = 1/R_a + 1/R_b + \dots$ equation is correct. A spreadsheet is included which can do this calculation for you.

In the example above, R_4 is 1K5 (1,500 ohms) and R_5 is 2K2 (2,200 ohms) so their combined resistance is given by $1/R_t = 1/1500 + 1/2200$ or $R_t = 892 \text{ ohms}$ (using a simple calculator). Apply a common-sense check to this result: If they had been two 1500 ohm resistors then the combined value would have been 750 ohms. If they had been two 2200 ohm resistors then the combined value would have been 1100 ohms. Our answer must therefore lie between 750 and 1100 ohms. If you came up with an answer of, say, 1620 ohms, then you know straight off that it is wrong and the arithmetic needs to be done again.

So, how about the voltages at points 'A' and 'B' in the circuit? As R_1 and R_2 are equal in value, they will have equal voltage drops across them for any given current. So the voltage at point 'A' will be half the battery voltage, i.e. 6 Volts.

Now, point 'B'. Resistors R_4 and R_5 act the same as a single resistor of 892 ohms, so we can just imagine two resistors in series: R_3 at 470 ohms and R_4+R_5 at 892 ohms. Common-sense rough check: as R_3 is only about half the resistance of R_4+R_5 , it will have about half as much voltage drop across it as the voltage drop across R_4+R_5 , i.e. about 4 Volts across R_3 and about 8 Volts across R_4+R_5 , so the voltage at point 'B' should work out at about 8 Volts.

We can use **Ohm's Law** to calculate the current flowing through point 'B':

Ohms = Volts / Amps, (or **Amps = Volts / Ohms** or **Volts = Ohms x Amps**)

$(470 + 892) = 12 / \text{Amps}$, so

$\text{Amps} = 12 / (470 + 892)$

$\text{Amps} = 12 / 1362$ or

$\text{Amps} = 0.00881 \text{ Amps}$ (8.81 milliamps).

Now that we know the current passing through (R4+R5) we can calculate the exact voltage across them:

$\text{Resistance} = \text{Volts} / \text{Amps}$ so

$892 = \text{Volts} / 0.00881$ or

$\text{Volts} = 892 \times 0.00881$

$\text{Volts} = 7.859 \text{ Volts}$.

As our common-sense estimate was 8 Volts, we can accept 7.86 Volts as being the accurate voltage at point 'B'.

The Potentiometer.

Just before we leave the subject of resistors and move on to more interesting subjects, we come across the term 'potentiometer'. This term is often shortened to 'pot' and many people use it to describe a variable resistor. I only mention this so that you can understand what they are talking about. A variable resistor is not a potentiometer and really should not be called one. You can skip the rest of this part as it is not at all important, but here is what a potentiometer is:

A fancy name for voltage is 'potential', so a circuit powered by a 12 Volt battery can be described as having a 'potential' of zero volts at the negative side of the battery and a 'potential' of plus twelve volts at the positive side of the battery. Ordinary folks like me would just say 'voltage' instead of 'potential'.

When a voltmeter is used to measure the voltage at any point in a circuit, it alters the circuit by drawing a small amount of current from the circuit. The voltmeter usually has a high internal resistance and so the current is very small, **but** even though it is a small current, it **does** alter the circuit. Consequently, the measurement made is not quite correct. Scientists, in years gone by, overcame the problem with a very neat solution - they measured the voltage without taking **any** current from the circuit - neat huh? They also did it with a very simple arrangement:

They used a sensitive meter to measure the current. This meter is built so that the needle is in a central position if no current is flowing. With a positive current flowing, the needle deflects to the right. With a negative current flowing, the needle moves to the left. They then connected a variable resistor 'VR1' across the same battery which was powering the circuit. The top end of VR1 is at +12 Volts (they called that 'a potential of +12 Volts') and the bottom end of VR1 is at zero volts or 'a potential of zero volts'.

By moving the slider of VR1, any voltage or 'potential' from zero volts to +12 Volts could be selected. To measure the voltage at point 'A' without drawing any current from the circuit, they would connect the meter as shown and adjust the variable resistor until the meter reading was exactly zero.

Since the meter reading is zero, the current flowing through it is also zero and the current taken from the circuit is zero. As no current is being taken from the circuit, the measurement is not affecting the circuit in any way - very

clever. The voltage on the slider of VR1 exactly matches the voltage at point 'A', so with a calibrated scale on the variable resistor, the voltage can be read off.

The slick piece of equipment made up from the battery, the variable resistor and the meter was used to measure the 'potential' (voltage) at any point and so was called a 'potentiometer'. So, please humour me by calling a variable resistor a 'variable resistor' and not a 'potentiometer'. As I said before, this is not at all important, and if you want to, you can call a variable resistor a 'heffalump' so long as you know how it works.

Semiconductors.

This section deals with discrete semiconductors. A later section deals with 'Integrated Circuits' which are large-scale semiconductor devices.

ORP12 Light-dependent resistor. This device has a high resistance in the dark and a low resistance in bright light. It can be placed in a circuit to create a switch which operates with an increase in light level or a decrease in light level:

In this version, the voltage at point 'A' controls the circuit. In darkness, the ORP12 has a resistance ten times greater than that of R1 which is 12,000 ohms. Consequently, the voltage at point 'A' will be high. As the light level increases, the resistance of the ORP12 falls, dragging the voltage at point 'A' downwards. As the variable resistor 'VR1' is connected from point 'A' to the ground rail (the -ve of the battery), its slider can be moved to select any voltage between 0 Volts and the voltage of 'A'. A slider point can be chosen to make the transistor switch off in daylight and on at night. To make the circuit trigger when the light level increases, just swap the positions of R1 and the ORP12.

The transistor shown is a BC109 although most transistors will work in this circuit. The BC109 is a cheap, silicon, NPN transistor. It can handle 100mA and 30V and can switch on and off more than a million times per second. It has three connections: the Collector, marked 'c' in the diagram, the Base, marked 'b' in the diagram and the Emitter, marked 'e' in the diagram.

As mentioned before, it has a very high resistance between the collector and the emitter when no current flows into the base. If a small current is fed into the base, the collector/emitter resistance drops to a very low value. The collector current divided by the base current is called the 'gain' of the transistor and is often called 'hfe'. A transistor such as a BC109 or a BC108 has a gain of about 200, though this varies from actual transistor to actual transistor. A gain of 200 means that a current of 200mA passing through the collector requires a current of 1mA through the base to sustain it. Specific information on the characteristics and connections of semiconductors of all kinds can be obtained free from the excellent website www.alldatasheet.co.kr which provides .pdf information files.

The BC109 transistor shown above is an NPN type. This is indicated by the arrow of the symbol pointing outwards. You can also tell by the collector pointing to the positive rail. There are similar silicon transistors constructed as PNP devices. These have the arrow in the transistor symbol pointing inwards and their collectors get connected, directly or indirectly, to the negative rail. This family of transistors are the earliest transistor designs and are called 'bi-polar' transistors.

These silicon transistors are so efficiently constructed that they can be connected directly together to give greatly increased gain. This arrangement is called a 'Darlington pair'. If each transistor has a gain of 200, then the pair give a gain of $200 \times 200 = 40,000$. This has the effect that a very, very small current can be used to power a load. The following diagram shows a Darlington pair used in a water-level detector. This type of alarm could be very useful if you are asleep on a boat which starts taking on water.

Here, (when the circuit is switched on), transistor TR1 has so little leakage current that TR2 is starved of base current and is hard off, giving it a high resistance across its collector/emitter junction. This starves the buzzer of voltage and keeps it powered off. The sensor is just two probes fixed in place above the acceptable water level. If the water level rises, the probes get connected via the water. Pure water has a high electrical resistance but this circuit will still work with pure water.

The odds are that in a practical situation, the water will not be particularly clean. The resistor R1 is included to limit the base current of TR1 should the sensor probes be short-circuited. Silicon bi-polar transistors have a base/emitter voltage of about 0.7V when fully switched on. The Darlington pair will have about 1.4V between the base of TR1 and the emitter of TR2, so if the sensor probes are short-circuited together, resistor R1 will have $6 - 1.4 = 4.6\text{V}$ across it. Ohms Law gives us the current through it as $R = V / A$ or $47,000 = 4.6 / A$ or $A = 4.6 / 47,000$ amps. This works out at 0.098mA which with a transistor gain of 40,000 would allow up to 3.9A through the buzzer. As the buzzer takes only 30mA or so, it limits the current passing through it, and TR2 can be considered to be switched hard on with the whole battery voltage across it.

NPN transistors are more common than PNP types but there is almost no practical difference between them. Here is the previous circuit using PNP transistors:

Not a lot of difference. Most of the circuit diagrams shown here use NPN types but not only are these not critical, but there are several ways to design any particular circuit. In general, the semiconductors shown in any circuit are seldom critical. If you can determine the characteristics of any semiconductor shown, any reasonably similar device can generally be substituted, especially if you have a general understanding of how the circuit works. Either of the two previous circuits can operate as a rain detector. A suitable sensor can easily be made from a piece of strip board with alternate strips connected together to form an interlacing grid:

Rain Sensor

Here, if a raindrop bridges between any two adjacent strips, the circuit will trigger and sound a warning.

The transistors in the circuit above are connected with their emitter(s) connected to the ground rail (the lower battery line shown in any circuit is considered to be “ground” unless it is specifically shown elsewhere). This connection method is called ‘common emitter’. The following circuit uses the transistor connected in ‘emitter follower’ mode. This is where the emitter is left to *follow* the base voltage - it is always 0.7V below it unless the base itself is driven below 0.7V:

Light-operated switch

This is almost the same as the light-operated circuit shown earlier. In this variation, the transistors are wired so that they work as an ‘emitter-follower’ which follows the voltage at point ‘A’ which rises as the light level drops and the resistance of the ORP12 increases. This causes the voltage across the relay to increase until the relay operates and closes its contacts. A relay is a voltage-operated mechanical switch which will be described in more detail later on.

The disadvantage of the above circuit is that as the light level decreases, the current through the relay increases and it may be a significant amount of current for some considerable time. If it was intended to power the unit with a battery then the battery life would be far shorter than it need be. What we would like, is a circuit which switched rapidly from the Off state to the On state even though the triggering input varied only slowly. There are several ways to achieve this, one of them being to modify the circuit to become a ‘Schmitt Trigger’:

Here, an additional transistor ('TR2') has changed the circuit operation significantly, with transistor TR3 switching fully on and fully off, rapidly. This results in the current through the relay being very low until the circuit triggers.

The circuit operates as follows. When the voltage at the base of TR1 is high enough, TR1 switches on, which causes the resistance between its collector and emitter to be so low that we can treat it as a short circuit (which is a nearly-zero resistance connection). This effectively connects the 10K and 1K8 resistors in series across the battery. The voltage at their connecting point (both the collector and emitter of TR1) will then be about 1.8 Volts. The two 18K resistors are in series across that voltage so the voltage at their junction will be half that; 0.9 Volts.

This puts the Base of TR2 at about 0.9 Volts and its emitter at 1.8 Volts. The base of TR2 is therefore not 0.7 Volts above its emitter, so no base/emitter current will flow in TR2, which means that TR2 is switched hard off. This means that the TR2 collector/emitter resistance will be very high. The voltage at the base of TR3 is controlled by the 1K8 resistor, the TR2 collector/emitter resistance (very high) and the 3K9 resistor. This pushes the base voltage of TR3 up to near the full battery voltage and as it is wired as an emitter-follower, its emitter voltage will be about 0.7 Volts below that. This means that the relay will have most of the battery voltage across it and so will switch hard on.

Some practical points: The current flowing into the base of TR3 comes via the 3K9 resistor. A 3K9 resistor needs 3.9 Volts across it for every 1 mA which flows through it. If the relay needs 150 mA to operate and TR3 has a gain of 300, then TR3 will need a base current of 0.5 mA to provide 150 mA of current through its collector/emitter junction. If 0.5 mA flows through the 3K9 resistor, there will be a voltage drop across it of some 2 Volts. The TR3 base/emitter voltage will be a further 0.7 Volts, so the voltage across the relay will be about $12.0 - 2.0 - 0.7 = 9.3$ Volts, so you need to be sure that the relay will work reliably at 9 Volts.

If you used a Darlington pair of transistors, each with a gain of 300, instead of TR3, then their combined base/emitter voltage drop would be 1.4 Volts, but they would only need a base current of $150 \text{ mA} / (300 \times 300) = 1/600 \text{ mA}$. That current would only drop 0.007 Volts across the 3K9 resistor, so the relay would receive 10.6 Volts.

So, how do you work out the gain of any particular transistor? The main working tool for electronics is a multimeter. This is a digital or analogue meter which can measure a wide range of things: voltage, current, resistance, ... The more expensive the meter, generally, the greater the number of ranges provided. The more expensive meters offer transistor testing. Personally, I prefer the older, passive multimeters. These are looked down on because they draw current from the circuit to which they are attached, but, because they do, they give reliable readings all the time. The more modern battery-operated digital multimeters will happily give incorrect readings as their battery runs down. I wasted two whole days, testing rechargeable batteries which appeared to be giving impossible performances. Eventually, I discovered that it was a failing multimeter battery which was causing false multimeter readings.

Transistor Testers.

For the moment, let us assume that no commercial transistor tester is to hand and we will build our own (or at least, discover how to build our own). The gain of a transistor is defined as the collector/emitter current divided by the base/emitter current. For example, if 1mA is flowing through the collector and 0.01mA is flowing into the base to sustain that collector flow, then the transistor has a gain of 100 times at 1mA. The transistor gain may vary when it is carrying different current loads. For the circuits we have been looking at so far, 1mA is a reasonable current at which to measure the transistor gain. So let's build a circuit to measure the gain:

Transistor Tester

With the circuit shown here, the variable resistor is adjusted until a collector current of 1mA is shown on the milliammeter and the gain of the transistor is then read off the scale on the variable resistor knob. The circuit is built into a small box containing the battery and with a socket into which the transistor can be plugged. The question then is, what values should be chosen for the resistor R1 and the variable resistor VR1?

Well, we might choose that the minimum gain to be displayed is 10. This would correspond to where the variable resistor slider is taken all the way up to point 'A' in the circuit diagram, effectively taking the variable resistor out of the circuit. If the transistor gain is 10 and the collector current is 1mA, then the base current will be 0.1mA. This current has to flow through the resistor R1 and it has a voltage of (9.0 - 0.7) Volts across it as the base/emitter voltage is 0.7 Volts when the transistor is on. Ohms Law gives us Ohms = Volts / Amps, which for the resistor R1 means Ohms = 8.3 / 0.0001 or 83,000 ohms, or 83K.

Rule of thumb: 1K provides 1mA if it has 1V across it, so 10K will give 0.1mA if it has 1 Volt across it. With 8.3 Volts across it, it needs to be 8.3 times larger to hold the current down to the required 0.1mA so the resistor should be 83K in size.

As 83K is not a standard size, we need to use two or more standard resistors to give that resistance. Nearest standard size below 83K is 82K, so we can use one 82K resistor and one 1K resistor in series to give the required 83K.

Suppose that we say that we would like to have 500 as the highest gain shown on our tester, then when VR1 is at its maximum value, it and R1 should provide 1/500 of the collector current of 1mA, i.e. 0.002mA or 0.000002 Amps. From Ohms Law again we get $VR1 + R1 = 4,150,000$ ohms or 4M15. Unfortunately, the largest value variable resistor available is 2M2 so the circuit as it stands, will not be able to cope.

Suppose we were to just use a 2M2 variable resistor for VR1, what transistor gain range could we display? Well Ohms Law ... lets us calculate the base current with 8.3 Volts across (83,000 + 2,200,000) ohms and from that the maximum transistor gain which would be 277.77 (at 1mA). You would buy a 'linear' standard carbon track variable resistor so that the change in resistance is steady as the shaft is rotated. The scale which you would make up would be in even steps and it would run from 10 at the minimum setting, to 278 at the highest setting.

But that is not what we wanted. We wanted to measure up to 500. But they don't make variable resistors big enough, so what can we do? Well, if we wanted, we could lower the battery voltage, which in turn would lower the resistor values. As a 9V battery is very convenient for this kind of circuit, lets not go down that route. We could add extra circuitry to drop the 9V battery voltage down to a lower value. The most simple solution is to add an extra resistor and switch to give two ranges. If we switched in an extra 2M2 resistor above VR1 then the circuit would measure transistor gains from 278 to just over 500 and all we would need to do would be to add a second scale for the VR1 pointer knob to move over. We could, provide extra ranges which overlap and which have more convenient scales to mark. The design is up to you.

Transistor Tester 2

The design covered above is not the only way to measure the transistor gain. A second way, which accepts that it is not so accurate, picks a set base current and measures the collector current as a guide to the gain. In this simple method, one or more resistor values are chosen to give gain ranges, and the milliammeter used to read the corresponding gain:

Transistor Tester 3

Here, resistor R1 might be chosen to give a collector current of 1mA (which is a full-scale deflection on the meter) when the transistor gain is 100. Resistor R2 might be picked to give a full-scale deflection for a gain of 200, R3 for a gain of 400, R4 for a gain of 600, and so on. Generally speaking, it is not essential to know the exact gain but any reasonable approximation to it is sufficient. You are normally selecting a transistor where you need a gain of 180, so it is not important if the transistor you pick has a gain of 210 or 215 - you are only avoiding transistors with gains below 180.

How do you work out the values of the resistors R1 to R4? Well, you probably won't expect this, but you use Ohms Law. Voltage drop is 8.3 Volts and the base current is given by the full-scale deflection's 1mA divided by the transistor gain for each range, i.e. 1/100 mA for R1, 1/200 mA for R2,... 1/600 mA for R4,...

The Diode.

One component which has been shown but not described is the diode or 'rectifier'. This is a device which has a very high resistance to current flowing in one direction and a very low resistance to current flowing in the opposite direction. The base/emitter junction of a transistor is effectively a diode and, at a push, can be used as such. A proper diode is cheap to buy and has far greater voltage and current handling capacities than the base/emitter junction of a transistor.

Diodes are mainly made from one of two materials: germanium and silicon. Germanium diodes are used with very small alternating currents such as radio signals coming from an aerial. This is because a germanium diode needs only 0.2 Volts or so to carry a current while silicon needs 0.6 to 0.7 Volts (same as a silicon transistor base/emitter junction). Germanium diodes (and transistors) are very sensitive to temperature change and so are normally restricted to low power circuits. One very neat application for a silicon diode is as an 'un-interruptible power supply' where mains failure is caught instantly:

Mains Unit Back-up Circuit

In this circuit, the mains voltage drives the Power Supply Unit which generates 12 Volts at point 'A'. This provides current to the Load. The diode has +12 Volts at 'A' and +12 Volts at point 'B' so there is no voltage drop across it and it will not carry current in either direction. This means that the battery is effectively isolated when the mains is functioning. If the Power Supply Unit output were to rise above its design level of +12 Volts, then the diode would block it from feeding current into the battery.

If the mains fails, the Power Supply Unit ('PSU') output will fall to zero. If the battery and diode were not there, the voltage at point 'A' would fall to zero, which would power-down the Load and possibly cause serious problems. For example, if the load were your computer, a mains failure could cause you to lose important data. With a battery back-up of this type, you would have time to save your data and shut your computer down before the battery ran out.

The circuit operates in a very simple fashion. As soon as the voltage at point 'A' drops to 0.7 Volts below the +12 Volts at point 'B', the diode starts feeding current from the battery to the Load. This happens in less than a millionth of a second, so the Load does not lose current. It would be worth adding a warning light and/or a buzzer to show that the mains has failed.

Diodes are also supplied packaged as a diode bridge, with four diodes enclosed inside. Usually intended for power supply rectification, they are not particularly fast-acting diodes, but are cheap and can carry a good deal of current. A common size is with the diodes rated at 1000 volts and able to carry 35 amps. Although there are many package types, a very common package looks like this:

The alternating signal is connected between two opposite corners and the pulsating DC is taken off from the other two terminals. The symbols shown above are normally marked on the flat face which is not seen in this picture. The package has a hole in the centre so that the metal case can be bolted to a heat-sink in order to keep the device reasonably cool when carrying large currents.

It is possible to connect the bridge in a different way and use it as a higher voltage double diode arrangement as shown here:

By skipping the alternating current ability and connecting to just the Plus and the Minus terminals, the package provides two pairs of diodes connected in series. This gives twice the voltage handling in both current paths and the rated current handling capacity in both of those two paths which are now connected across each other, which doubles the current handling capacity. The diagram shows how three ordinary, cheap 1000V 35 amp bridges can be connected to give one 70 amp 6000V composite diode.

Diodes are specified by their voltage handling capacity and their current-carrying capacity and the speed at which they can switch on and off. For power supplies where the frequency is very low, any diode will do, but there are circuits where the switching is needed hundreds of thousand times per second and so the diode specification sheets need to be checked to see what frequency can be handled by any particular diode. Those data sheets can be downloaded free from <http://www.alldatasheet.co.kr/>.

One other thing which needs to be checked for some circuits is the voltage needed to get the diode to switch on. Two common materials used when making diodes are silicon and germanium. Germanium types have a low forward voltage of around 0.2 volts typically which silicon has about a 0.6 volt threshold generally. These voltage figures vary enormously as the current through the diode increases. Circuits which use very low voltages need germanium diodes such as the 1N34.

Light-Emitting Diodes.

There is a widely used variation of the diode which is extremely useful, and that is the Light Emitting Diode or 'LED'. This is a diode which emits light when carrying current. They are available in red, green, blue, yellow or white light versions. Some versions can display more than one colour of light if current is fed through their different electrical connections.

LEDs give a low light level at a current of about 8 or 10 mA and a bright light for currents of 20 to 30 mA. If they are being used with a 12 Volt system, then a series resistor of 1K to 330 ohms is necessary. LEDs are robust devices, immune to shock and vibration. They come in various diameters and the larger sizes are very much more visible than the tiny ones.

Thyristors ("SCR"s) and Triacs.

Another version of the diode is the Silicon Controlled Rectifier or 'Thyristor'. This device carries no current until its gate receives an input current. This is just like the operation of a transistor but the SCR once switched on, stays on even though the gate signal is removed. It stays on until the current through the SCR is forced to zero, usually by the voltage across it being removed. SCRs are often used with alternating voltages (described below) and this causes the SCR to switch off if the gate input is removed. SCRs only operate on positive voltages so they miss half of the power available from alternating power supplies. A more advanced version of the SCR is the 'Triac' which operates in the same way as an SCR but handles both positive and negative voltages.

Opto-Isolators.

Another very useful variation on the LED is the Opto-Isolator. This device is a fully enclosed LED and light-sensitive transistor. When the LED is powered up, it switches the transistor on. The big advantage of this device is that the LED can be in a low voltage, low power sensing circuit, while the transistor can be in a completely separate, high voltage, high power circuit. The opto-isolator isolates the two circuits completely from each other. It is a very useful, and very popular, low-cost device.

Alternating Current.

A battery provides a constant voltage. This is called a Direct Current or 'DC' source of power. When a circuit is connected to a battery, the positive rail is always positive and the negative rail is always negative.

If you connect a battery to a circuit through a double-pole changeover switch as shown here:

When the changeover switch is operated, the battery is effectively turned over or inverted. This circuit is called an 'inverter' because it repeatedly inverts the supply voltage. If the switch is operated on a regular, rapid basis, the graph of the output voltage is as shown on the right. This is a 'square wave' voltage and is used extensively in electronic equipment. It is called alternating current or 'AC' for short. SCRs and Triacs can be used conveniently with supply voltages of this type. Mains voltage is also AC but is rather different:

Mains voltage varies continuously in the form of a sine wave. In Britain, the mains voltage is described as '240 Volts AC' and it cycles up and down 50 times per second, i.e. 50 positive peaks and 50 negative peaks in one second. It would be reasonable to assume that each voltage peak would be 240 Volts but this is not the case. Even though the supply is described as 240 Volts, it peaks at the square root of 2 times greater than that, i.e. 339.4 Volts. The actual supply voltage is not particularly accurate, so any device intended for mains use should be rated to 360 Volts. In America, the supply voltage is 110 Volts AC and it cycles 60 times per second, peaking at plus and minus 155 Volts. Later on, you will see how one or more diodes can be used to convert AC to DC in a unit which is sold as a 'mains adapter' intended to allow battery operated equipment be operated from the local mains supply.

Coils ("Inductors") and Solenoids.

If you take a cardboard tube, any size, any length, and wind a length of wire around it, you create a very interesting device. It goes by the name of a 'coil' or an 'inductor' or a 'solenoid'.

This is a very interesting device with many uses. It forms the heart of a radio receiver, it used to be the main component of telephone exchanges, and most electric motors use several of them. The reason for this is if a current is passed through the wire, the coil acts in exactly the same way as a bar magnet:

diode is connected so that no current flows through it from the battery positive to the 'ground' line (the battery negative). On the surface, it looks as if it has no use in this circuit. In fact, it is a very important component which protects transistor TR3 from damage.

The relay coil carries current when transistor TR3 is on. The emitter of transistor TR3 is up at about +10 Volts. When TR3 switches off, it does so rapidly, pushing the relay connection from +10 Volts to 0 Volts. The relay coil reacts in a most peculiar way when this happens, and instead of the current through the relay coil just stopping, the voltage on the end of the coil connected to the emitter of TR3 keeps moving downwards. If there is no diode across the relay, the emitter voltage is forced to briefly overshoot the negative line of the circuit and gets dragged down many volts below the battery negative line. The collector of TR3 is wired to +12 Volts, so if the emitter gets dragged down to, say, -30 Volts, TR3 gets 42 Volts placed across it. If the transistor can only handle, say, 30 Volts, then it will be damaged by the 42 Volt peak.

The way in which coils operate is weird. But, knowing what is going to happen at the moment of switch-off, we deal with it by putting a diode across the coil of the relay. At switch-on, and when the relay is powered, the diode has no effect, displaying a very high resistance to current flow. At switch-off, when the relay voltage starts to plummet below the battery line, the diode effectively gets turned over into its conducting mode. When the voltage reaches 0.7 Volts below the battery negative line, the diode starts conducting and pins the voltage to that level until the voltage spike generated by the relay coil has dissipated. The more the coil tries to drag the voltage down, the harder the diode conducts, stifling the downward plunge. This restricts the voltage across transistor TR3 to 0.7 Volts more than the battery voltage and so protects it.

Solenoid coils can be very useful. Here is a design for a powerful electric motor patented by the American, Ben Teal, in June 1978 (US patent number 4,093,880). This is a very simple design which you can build for yourself if you want. Ben's original motor was built from wood and almost any convenient material can be used. This is the top view:

And this is the side view:

Ben has used eight solenoids to imitate the way that a car engine works. There is a crankshaft and connecting rods, as in any car engine. The connecting rods are connected to a slip-ring on the crankshaft and the solenoids are given a pulse of current at the appropriate moment to pull the crankshaft round. The crankshaft receives four pulls on every revolution. In the arrangement shown here, two solenoids pull at the same moment.

In the side view above, each layer has four solenoids and you can extend the crankshaft to have as many layers of four solenoids as you wish. The engine power increases with every layer added. Two layers should be quite adequate as it is a powerful motor with just two layers.

An interesting point is that as a solenoid pulse is terminated, its pull is briefly changed to a push due to the weird nature of coils. If the timing of the pulses is just right on this motor, that brief push can be used to increase the power of the motor instead of opposing the motor rotation. This feature is also used in the Adams motor described in the 'Free-Energy' section of this document.

The strength of the magnetic field produced by the solenoid is affected by the number of turns in the coil, the current flowing through the coil and the nature of what is inside the coil 'former' (the tube on which the coil is wound). In passing, there are several fancy ways of winding coils which can also have an effect, but here we will only talk about coils where the turns are wound side by side at right angles to the former.

1. Every turn wound on the coil, increases the magnetic field. The thicker the wire used, the greater the current which will flow in the coil for any voltage placed across the coil. Unfortunately, the thicker the wire, the more space each turn takes up, so the choice of wire is somewhat of a compromise.

2. The power supplied to the coil depends on the voltage placed across it. $\text{Watts} = \text{Volts} \times \text{Amps}$ so the greater the Volts, the greater the power supplied. But we also know from Ohm's Law that $\text{Ohms} = \text{Volts} / \text{Amps}$ which can also be written as $\text{Ohms} \times \text{Amps} = \text{Volts}$. The Ohms in this instance is fixed by the wire chosen and the number of turns, so if we double the Voltage then we double the current.

For example: Suppose the coil resistance is 1 ohm, the Voltage 1 Volt and the Current 1 Amp. Then the power in Watts is Volts x Amps or 1×1 which is 1 Watt.

Now, double the voltage to 2 Volts. The coil resistance is still 1 ohm so the Current is now 2 Amps. The power in Watts is Volts x Amps or 2×2 which is 4 Watts. Doubling the voltage has quadrupled the power.

If the voltage is increased to 3 Volts. The coil resistance is still 1 ohm so the Current is now 3 Amps. The power in Watts is Volts x Amps or 3×3 which is 9 Watts. The power is Ohms x Amps squared, or $\text{Watts} = \text{Ohms} \times \text{Amps} \times \text{Amps}$. From this we see that the voltage applied to any coil or solenoid is critical to the power developed by the coil.

3. What the coil is wound on is also of considerable importance. If the coil is wound on a rod of soft iron covered with a layer of paper, then the magnetic effect is increased dramatically. If the rod ends are tapered like a flat

screwdriver or filed down to a sharp point, then the magnetic lines of force cluster together when they leave the iron and the magnetic effect is increased further.

If the soft iron core is solid, some energy is lost by currents flowing round in the iron. These currents can be minimised by using thin slivers of metal (called 'laminations') which are insulated from each other. You see this most often in the construction of transformers, where you have two coils wound on a single core. As it is convenient for mass production, transformers are usually wound as two separate coils which are then placed on a figure-of-eight laminated core.

Transformers.

Transformers are used to alter the voltage of any alternating current power source. If the alteration increases the output voltage, then the transformer is called a 'step-up' transformer. If the output voltage is lower than the input voltage then it is called a 'step-down' transformer. If the voltages are the same, it is called an 'isolation' transformer. A common construction looks like this:

The Coil bobbin sits on the section of the laminations marked 'A' above. The coil is wound on its bobbin former, first one winding and then the second winding. The bobbin is then placed on the central part of the 'E' shaped laminations and then completely surrounded by the laminations when the crossbar is placed on the top. The mounting strap is used to hold the two sets of laminations together and provide mounting lugs for attaching the transformer to a chassis. There are typically, twenty laminations in each set and every lamination is insulated from the adjoining laminations.

If you want to change the voltage of a battery supply, it is possible to build an electronic circuit to generate an alternating voltage and then use a transformer to change that alternating voltage to whatever voltage you want. The most common form of this, is for generating mains voltage from a 12 Volt car battery, so that mains equipment can be run in remote locations, such as boats, caravans, etc. These circuits are called 'inverters' and they are very popular pieces of equipment. The voltage in the secondary coil of any transformer is determined by the ratio of the turns in the primary and secondary windings.

For example; if there is a 10 Volt alternating voltage available and you have a transformer which has 100 turns in the primary coil and 1000 turns in the secondary coil. If you connect the 10 Volts across the primary, there will be 100 Volts generated across the secondary coil.

Instead, if you connect the 10 Volts across the secondary coil, a voltage of 1 Volts will be generated across the primary winding. This is because there is a 10:1 ratio between the two windings. The Law of Conservation of Energy applies to transformers as it does to everything else. The power input to the primary winding will be the same as the power in the secondary winding minus the losses. The losses, in this case, will be a temperature rise of the whole transformer. If the current passed through the transformer is well below its rated capacity, then the losses will be small. The important point is that 10 Volts at 1 Amp into the primary winding will generate 100 Volts in the secondary, but at somewhat less than 0.1 Amps: Power Input is 10 Watts and Power Output is almost 10 Watts. The voltage has been raised to 100 Volts but the potential current draw has been reduced from 1 Amp to 0.1 Amps (100 mA).

In practice, the thickness of the wire used in the windings is very important. If the voltage to be placed across the winding is high, then the wire diameter will be small. Coil windings have fairly low resistances but this is not critical in circuits as coils operate in a peculiar way. Coils have AC 'impedance' in addition to their DC 'resistance'. While Direct Current (from a battery, say) can flow quite easily through a coil with low resistance, Alternating Current may have a hard job getting through the coil due to its high 'impedance'. Sometimes, coils are used to choke off any AC ripple (interference) coming along a DC power cable. When a coil is used for this purpose it is called a 'choke'. Each coil has its own resonant frequency and at that frequency it is very difficult for AC to get through the coil. Crystal set radios work on that principle:

Crystal Set Radio

Here, the aerial picks up every radio station broadcasting in the area. These are all at different frequencies and they all head down the aerial wire, looking for the easiest path to the earth connection. Most of them run through the coil with no problem whatsoever. If the resonant frequency of the coil matches the frequency of one of the radio stations, then that radio signal (and **only** that signal) finds it very hard to get through the coil and looks for an easier path to earth. The next easiest path is through the diode and the headphones, so the signal goes that way. The diode blocks part of the signal which generates the sound of the radio broadcast in the headphones.

This system works very well indeed if there is a good radio signal. A germanium diode is used as the radio signal voltage is very small and a germanium diode operates on 0.2 Volts while a silicon diode needs 0.7 Volts to operate. That difference is significant at these very low voltages. The resonant frequency of the coil depends on the number of turns in the coil. In this design, the coil has a slider which allows the number of turns to be altered and so, different radio stations to be tuned in.

Rectification and Power Supplies.

We now have the question of how do we turn an alternating voltage into a constant 'direct' voltage. The crystal radio set operates by chopping off half of the alternating radio signal. If we were to do this to the output from a mains transformer with an output of say, 12 Volts AC, the result is not very satisfactory:

Half-wave rectification

Full-wave rectification

Here, we have the situation shown in the upper diagram. The output consists of isolated pulses at 50 per second. You will notice that there is **no** output power for half of the time. The negative part of the waveform is blocked by the high resistance of the diode while the positive part of the waveform is allowed through by the low resistance of the 'forward-biased' diode. It should be remembered that the diode drops 0.7 Volts when conducting so the output of the half-wave rectified transformer will be 0.7 Volts lower than the transformer's actual output voltage.

If four diodes are used instead of one, they can be arranged as shown in the lower diagram. This arrangement of diodes is called a 'bridge'. Here the positive part of the waveform flows through the upper blue diode, the load 'L' and on through the lower blue diode. The negative part flows through the left hand red diode, the load and then the right hand red diode. This gives a much better output waveform with twice the power available. The output voltage will be 1.4 Volts less than the transformer output voltage as there are two silicon diodes in the supply chain.

The output from even the full-wave rectifier is still unsatisfactory as there is a voltage drop to zero volts 100 times per second. Only a few devices operate well with a power supply like that, an incandescent bulb as used in a car can use this output, but then, it could use the original AC supply without any rectification. We need to improve the output by using a reservoir device to supply current during those moments when the voltage drops to zero. The device we need is a **Capacitor** which used to be called a 'condenser'. The circuit of a mains unit using a capacitor is shown here:

This produces a much better result as the capacitor stores some of the peak energy and gives it out when the voltage drops. If the load on the unit is light with not very much current taken from it, the output voltage is quite good. However, if the current drain is increased, the output voltage gets dragged down 100 times per second. This voltage variation is called 'ripple' and if the unit is supplying an audio system or a radio, the ripple may well be heard as an annoying hum. The larger the capacitor for any given current draw, the smaller the ripple.

To improve the situation, it is normal to insert an electronic control circuit to oppose the ripple:

This circuit uses one new component, a new variety of diode called a 'Zener' diode. This device has an almost constant voltage drop across it when its current-blocking direction breaks down. The diode is designed to operate in this state to provide a reference voltage. The circuit merely uses a tiny current from the top of the zener diode to drive the Darlington pair emitter-follower transistors used to provide the output current.

With this circuit, when the output current is increased, the resistance of the transistor pair automatically reduces to provide more current without varying the output voltage. The 1K resistor is included to give the transistors a completed circuit if no external equipment is connected across the output terminals. The zener diode is chosen to give 1.4 Volts more than the required output voltage as the two transistors drop 1.4 Volts when conducting.

You should note that the output transistor is dropping 6 Volts at the full supply current. Watts = Volts x Amps so the power dissipated by the transistor may be quite high. It may well be necessary to mount the transistor on an aluminium plate called a 'heat sink' to keep it from overheating. Some power transistors, such as the 2N3055, do not have the case isolated from the active parts of the transistor. It is good practice to use a mica gasket between the transistor and the heat-sink as it conducts then heat without making an electrical connection to the metal heat-sink.

A capacitor, being an electrical reservoir, can be used as part of a timer circuit. If the current flow into it is restricted by passing it through a resistor. The length of time between starting the flow on an empty capacitor, and the voltage across the capacitor reaching some chosen level, will be constant for a high-quality capacitor.

As the voltage increase tails off, it becomes more difficult to measure the difference accurately, so if the capacitor is to be used for generating a time interval, it is normal to use the early part of the graph area where the line is fairly straight and rising fast.

The Voltage Doubler.

It is possible to increase the output voltage of a transformer although this does reduce its ability to supply current at that voltage. The way that this is done is to feed the positive cycles into one storage capacitor and the negative cycles into a second reservoir capacitor. This may sound a little complicated, but in reality, it isn't. A circuit for doing this is shown here:

With this circuit, the transformer output is some voltage, say "V" volts of AC current. This output waveform is fed to capacitor "C1" through diode "D1" which lops off the negative part of the cycle. This produces a series of positive half-cycles which charge up capacitor "C1" with a positive voltage of "V".

The other half of the output is fed to capacitor "C2" through diode "D2" which cuts off the positive part of the cycle, causing capacitor "C2" to develop a voltage of -V across it. As the two capacitors are 'in series' and not placed across each other, their voltages add up and produce twice the transformer output voltage.

A word of warning here. The transformer is producing an AC waveform and these are marked with the **average** voltage of the waveform, which is usually a sine wave. The peak voltage of a sinewave is 41% greater than this, so if your transformer has an AC output of 10 volts, then the peaks fed to the capacitors will be about 14.1 volts. If

there is no current draw from the capacitors (that is, with the load switched off), then each capacitor will charge to this 14.1 volts and the overall output voltage will be 28.2 volts and **not** the 20 volts which you might expect. You need to understand that as this is only a half-wave supply, there will be considerable ripple on the output voltage if the current draw is high.

Using one additional smoothing capacitor and paying attention to the voltage ratings of the capacitors, the 28 volts supply circuit might be like this:

Multivibrators: The Bistable.

The number of electronic circuits which can be built with basic components such as resistors, capacitors, transistors, coils, etc. is limited only by your imagination and needs. Here is a circuit where two transistors operate as a pair:

This circuit has two stable states and so it is called a “bi” “stable” or “bistable” circuit. It is important to understand the operation of this simple and useful circuit.

If press-button switch ‘A’ is pressed, it short-circuits the base/emitter junction of transistor TR1. This prevents any current flowing in the base/emitter junction and so switches TR1 hard off. This makes the voltage at point ‘C’ rise as high as it can. This leaves transistor TR2 powered by R1 and R2 which have 11.3 Volts across them and switches TR2 hard on.

This pulls point ‘D’ down to about 0.1 Volts. This happens in less than a millionth of a second. When the press-button switch ‘A’ is released, transistor TR1 does not switch on again because its base current flows through resistor R3 which is connected to point ‘D’ which is far, far below the 0.7 Volts needed to make TR1 start conducting.

The result is that when press-button ‘A’ is pressed, transistor TR2 switches on and stays on even when press-button ‘A’ is released. This switches transistor TR3 off and starves the Load of current. This is the first ‘stable state’.

The same thing happens when press-button ‘B’ is pressed. This forces transistor TR2 into its ‘off’ state, raising point ‘D’ to a high voltage, switching transistor TR3 hard on, powering the Load and holding transistor TR1 hard off. This is the second of the two ‘stable states’.

In effect, this circuit ‘remembers’ which press-button was pressed last, so millions of these circuits are used in computers as Random Access Memory (‘RAM’). The voltage at point ‘C’ is the inverse of the voltage at point ‘D’, so if ‘D’ goes high then ‘C’ goes low and if ‘D’ goes low, then ‘C’ goes high. In passing, the output at ‘D’ is often called ‘Q’ and the output at ‘C’ is called ‘Q-bar’ which is shown as the letter Q with a horizontal line drawn above it. This is shown on the next circuit diagram.

A minor variation of this circuit allows a load to be energised when the circuit is powered up:

When powered down, the capacitor 'C1' in this circuit is fully discharged through resistor 'R6'. When the 12 Volts supply is connected to the circuit, capacitor C1 does not charge instantly and so holds the base of TR2 down below 0.7 Volts for much longer than it takes for transistor TR1 to switch on (which, in turn, holds TR2 hard off). Mind you, if it is not necessary to have the Load held powered on indefinitely, then an even more simple circuit can do this:

Here, when the switch is closed, both sides of the capacitor C1 are at +12 Volts and this causes the 1K8 resistor to conduct heavily, driving the transistor and powering the load. The capacitor charges rapidly through the transistor and reaches the point at which it can no longer keep the transistor switched on. When the battery is switched off, the 1M resistor discharges the capacitor, ready for the next time the battery is connected.

the Monostable Multivibrator.

The monostable has one stable state and one unstable state. It can be flipped out of its stable state but it will 'flop' back into its stable state. For that reason, it is also known as a 'flip-flop' circuit. It is similar to a bistable circuit, but one of the cross-link resistors has been replaced by a capacitor which can pass current like a resistor, but only for a limited amount of time, after which, the capacitor becomes fully charged and the current flow stops, causing the 'flop' back to the stable state once more.

In this circuit, the 'R' resistor and the 'C' capacitor values determine how long the monostable will be in its unstable state. The circuit operates like this:

1. In the stable state, transistor TR1 is off. Its collector voltage is high, pushing the left hand side of capacitor 'C' to near +12 Volts. As the right hand side of capacitor 'C' is connected to the base of TR2 which is at 0.7 Volts, the capacitor gets charged to about 11.3 Volts.
2. The press-button switch is operated briefly. This feeds current through its 10K resistor to the base of transistor TR1, switching it hard on. This drops the collector voltage of TR1 to near 0 Volts, taking the left hand side of the capacitor with it.
3. As the voltage across a capacitor can't change instantly, the right hand side of the capacitor drives the base of transistor TR2 down below 0.7 Volts, causing TR2 to switch off.
4. The circuit can't hold TR2 in its 'off' state for ever. The resistor 'R' feeds current into the capacitor, forcing the voltage at the base of TR2 steadily upwards until the voltage reaches 0.7 Volts and transistor TR2 switches on again, forcing TR1 off again (provided that the press-button switch has been released). This is the stable state again. If the press-button switch is held on, then both transistors will be on and the output voltage will still be low. Another output pulse will not be generated until the press-button is let up and pressed again.

This circuit could be used to switch a microwave oven on for any chosen number of seconds, create a delay on your home-built burglar alarm, to give you time to switch it off after walking through your front door, operate a solenoid valve to feed a pre-determined quantity of beverage into a bottle on a production line, or whatever...

The Astable Multivibrator.

The astable circuit is the monostable with a second capacitor added so that neither state is stable. This results in the circuit flopping backwards and forwards continuously:

The rate of switching is controlled by the R1/C1 and R2/C2 combinations. The load's ON time to its OFF time is called the 'mark-space' ratio, where the ON period is the 'mark' and the OFF period is the 'space'. If you choose to use electrolytic capacitors which have their own polarity, then the +ve end of each capacitor is connected to the transistor collector.

While it is good to understand how these multivibrator circuits operate and can be built, nowadays there are pre-built circuits encased in a single package which you are much more likely to choose to use. These are called Integrated Circuits or 'ICs' for short. We will be discussing these shortly. Before we do, notice that in the circuit above, transistor TR3 has been changed to a new variety called a **Field Effect Transistor** ('FET'). This type of transistor is newer than the 'bipolar' transistors shown in the earlier circuits. FETs come in two varieties: 'n-channel' which are like NPN transistors and 'p-channel' which are like PNP transistors.

FETs are more difficult to make but have now reached a level of cost and reliability which makes them very useful indeed. They require almost no base current (called 'gate' current with this type of transistor) which means that they have almost no effect on any circuit to which they are attached. Also, many of them can handle large currents and boast major power handling capabilities. Because of this, it is usual to see them packaged with a metal plate mounting, ready to be bolted to an aluminium heat-sink plate to help dissipate the heat generated by the large amount of power flowing through them. The 'RFP50N06' shown above can handle up to 50 Volts and carry up to 60 Amps, which is serious power handling.

Inverters and Truth Tables.

Consider the following circuit:

If neither of the press-button switches are operated, the transistor has no base/emitter current flow and so it is off. This places the collector voltage at 'C' near the positive rail (+5 Volts).

If press-button switch 'A' is operated, the base voltage tries to rise to half of the battery voltage but doesn't make it because the transistor base pins it down to 0.7 Volts. This feeds base current to the transistor, switching it hard on and causing the output at 'C' to drop to nearly 0 Volts.

If press-button switch 'B' is operated (don't do this when switch 'A' is closed or you will get a very high 'short-circuit' current flowing directly through the two switches) it has no effect on the output voltage which will stay high.

If we re-draw the circuit like this:

TRUTH TABLE	
Input A	Output C
0	1
1	0

Key:
0 = Less than 0.5 Volts
1 = More than 3.5 Volts

We can see that if the voltage at the input 'A' is taken high, then the output voltage at 'C' will be low. If the voltage at the input 'A' is taken low, then the output voltage at 'C' will be high. A circuit which does this is called an 'Inverter' because it 'inverts' (or 'turns upside down') the input voltage.

We can summarise this operation in a table. Personally, I would call the table an 'Input/Output' table, but for no obvious reason, the standard name is a 'Truth' table. The purpose of this table is to list all of the possible inputs and show the corresponding output for each input.

Another standard, is to substitute '1' for 'High Voltage' and '0' for 'Low Voltage'. You will notice that many items of electrical and electronic equipment have these symbols on the ON / OFF switch. In computer circuitry (hah! you didn't notice that we had moved to computer circuits, did you?), the '0' represents any voltage below 0.5 Volts and the '1' represents any voltage above 3.5 Volts. Many, if not most, computers operate their logic circuits on 5 Volts. This Inverter circuit is a 'logic' circuit.

A criticism of the above circuit is that its input resistance or 'impedance' is not particularly high, and its output impedance is not particularly low. We would like our logic circuits to be able to operate the inputs of eight other logic circuits. The jargon for this is that our circuit should have a 'fan-out' of eight.

Let's go for a simple modification which will improve the situation:

Here, The input impedance has been increased by a factor of 100 by using a Darlington pair of transistors which need far less base current, and so can have a much higher input resistor.

Unfortunately, the output impedance is still rather high when the transistors are in their OFF state as any current taken from the positive line has to flow through the 1K8 (1800 ohm) resistor. But we need this resistor for when the transistors are in their ON state. We really need to change the 1K8 resistor for some device which has a high resistance at some times and a low resistance at other times. You probably have not heard of these devices, but they are called 'transistors'.

There are several ways to do this. We might choose to use PNP transistors (we normally use NPN types) and connect these in place of the 1K8 resistor. Perhaps we might use a circuit like this:

This circuit is starting to look complicated and I don't like complicated circuits. It is not as bad as it looks. The NPN transistors at the bottom are almost the same as the previous circuit. The only difference is that the collector load is now two 100 ohm resistors plus the resistance of the two transistors. If the PNP transistors are OFF when the NPN transistors are ON, then the circuit loading on the NPN transistors will be negligible and the whole of the NPN transistors output will be available for driving external circuits through the lower 100 ohm resistor (a large 'fan-out' for the '0' logic state). To make sure that the PNP transistors are hard off before the NPN transistors start to switch on, the resistor 'R1' needs to be selected carefully.

The PNP transistors are an exact mirror image of the NPN side, so resistor R2 needs to be selected carefully to ensure that the NPN transistors are switched hard OFF before the PNP transistors start to switch ON.

You need not concern yourself unduly with that circuit, because you will almost certainly use an Integrated Circuit rather than building your own circuit from 'discrete' components. An Integrated Circuit containing six complete inverters is the 7414 which is shown above. This comes in a small black case with two rows of 7 pins which make it look a bit like a caterpillar. Because there are two row of pins, the packaging is called "Dual In-Line" or "DIL" for short.

Now, consider the following circuit:

TRUTH TABLE		
Input A	Input B	Output C
0	0	1
0	1	0
1	0	0
1	1	0

0 = Low voltage 1 = High Voltage

This circuit operates the same way as the Inverter circuit, except that it has two inputs ('A' and 'B'). The output voltage at 'C' will be low if either, 'A' OR 'B' or both, of the inputs is high. The only time that the output is high, is when both Input 'A' and Input 'B' are low. Consequently, the circuit is called an "OR" gate. Strictly speaking, because the output voltage goes Down when the input voltage goes Up, it is called a "Not OR" gate, which gets shortened to a "NOR" gate. In this context, the word "not" means "inverted". If you fed the output 'C' into an inverter circuit, the resulting circuit would be a genuine "OR" gate. The digital circuit symbols for an AND gate, a NAND gate, an OR gate and a NOR gate are:

Gating.

These common chips are usually supplied with 2, 4 or 8 inputs. So, why is it called a "Gate" - isn't it just a double inverter? Well, yes, it **is** a double inverter, but a double inverter acts as a gate which can pass or block an electronic signal. Consider this circuit:

Here, transistors 'TR1' and 'TR2' are connected to form an astable (multivibrator). The astable runs freely, producing the square wave voltage pattern shown in red. Transistor 'TR3' passes this voltage signal on. TR3 inverts the square wave, but this has no practical effect, the output being the same frequency square wave as the signal taken from the collector of TR2.

If the press-button switch at point 'A' is operated, a current is fed to the base of TR3 which holds it hard on. The voltage at point 'C' drops to zero and stays there. The square wave signal coming from the collector of TR2 is blocked and does not reach the output point 'C'. It is as if a physical 'gate' has been closed, blocking the signal from reaching point 'C'. As long as the voltage at point 'A' is low, the gate is open. If the voltage at point 'A' goes high, the gate is closed and the output is blocked.

There is no need for a manual switch at point 'A'. Any electronic switching circuit will do:

Here, a slow-running astable is substituted for the manual switch. When the output voltage of 'Astable 2' goes high, it switches the gate transistor 'TR3', holding it hard on and blocking the square-wave signal from 'Astable 1'. When the output voltage of 'Astable 2' goes low, it frees transistor 'TR3' and it then passes the 'Astable 1' signal through again. The resulting gated waveform is shown in red at point 'C' and it is bursts of signal, controlled by the running rate of 'Astable 2'. This is the sort of waveform which Stan Meyer found very effective in splitting water into Hydrogen and Oxygen (see Chapter 10).

This circuit could also be drawn as:

The small circle on the output side of logic devices is to show that they are inverting circuits, in other words, when the input goes up, the output goes down. The two logic devices we have encountered so far have had this circle: the Inverter and the NAND gate.

If you wish, you can use a NAND gate chip which has the circuitry also built as a Schmitt trigger, which as you will recall, has a fast-switching output even with a slowly moving input. With a chip like that, you can get three different functions from the one device:

If the two inputs of a NAND gate are connected together, then the output will always be the opposite of the input, i.e. the gate acts as an inverter. This arrangement also works as a Schmitt Trigger due to the way the NAND gate circuitry is built. There are several packages built with this type of circuitry, the one shown here is the “74132” chip which contains four “dual-input” NAND gates. Gates can have almost any number of inputs but it is rare to need more than two in any given circuit. Another chip with identical pin connections is the **4011** chip (which is not a Schmitt circuit). This ‘quad dual-input’ NAND gate package uses a construction method called “CMOS” which is very easily damaged by static electricity until actually connected into a circuit. CMOS chips can use a wide range of voltages and take very little current. They are cheap and very popular

The number of devices built into an Integrated Circuit is usually limited by the number of pins in the package and one pin is needed for one connection to ‘the outside world’. Packages are made with 6 pins (typically for opto-isolators), 8 pins (many general circuits), 14 pins (many general circuits, mostly computer logic circuits), 16 pins (ditto, but not as common) and then a jump to large numbers of pins for Large Scale devices such as microprocessors, memory chips, etc. The standard IC package is small:

Prototype circuits are often built on ‘strip board’ which is a stiff board with strips of copper running along one face, and punched with a matrix of holes. The strips are used to make the electrical connections and are broken where necessary. This strip board is usually called “Veroboard”:

Nowadays, the strip board holes are spaced 2.5 mm (1/10”) apart which means that the gaps between the copper strips is very small indeed. I personally, find it quite difficult to make good solder joints on the strips without the solder bridging between two adjacent strips. Probably, a smaller soldering iron is needed. I need to use an 8x magnifying glass to be sure that no solder bridging remains in place before a new circuit is powered up for the first

time. Small fingers and good eyesight are a decided advantage for circuit board construction. The narrow spacing of the holes is so that the standard IC DIL package will fit directly on the board.

Circuits built using computer circuitry, can experience problems with mechanical switches. An ordinary light switch turns the light on and off. You switch it on and the light comes on. You switch it off and the light goes off. The reason it works so well is that the light bulb takes maybe, a tenth of a second to come on. Computer circuits can switch on and off 100,000 times in that tenth of a second, so some circuits will not work reliably with a mechanical switch. This is because the switch contact bounces when it closes. It may bounce once, twice or several times depending on how the switch is operated. If the switch is being used as an input to a counting circuit, the circuit may count 1, 2 or several switch inputs for one operation of the switch. It is normal to “de-bounce” any mechanical switch. This could be done using a couple of NAND gates connected like this:

The NAND Latch.

Here, the mechanical switch is buffered by a ‘latch’. When the ‘Set’ switch is operated, the output goes low. The unconnected input of gate ‘1’ acts as if it has a High voltage on it (due to the way the NAND gate circuit was built). The other input is held low by the output of gate ‘2’. This pushes the output of gate ‘1’ high, which in turn, holds the output of gate ‘2’ low. This is the first stable state.

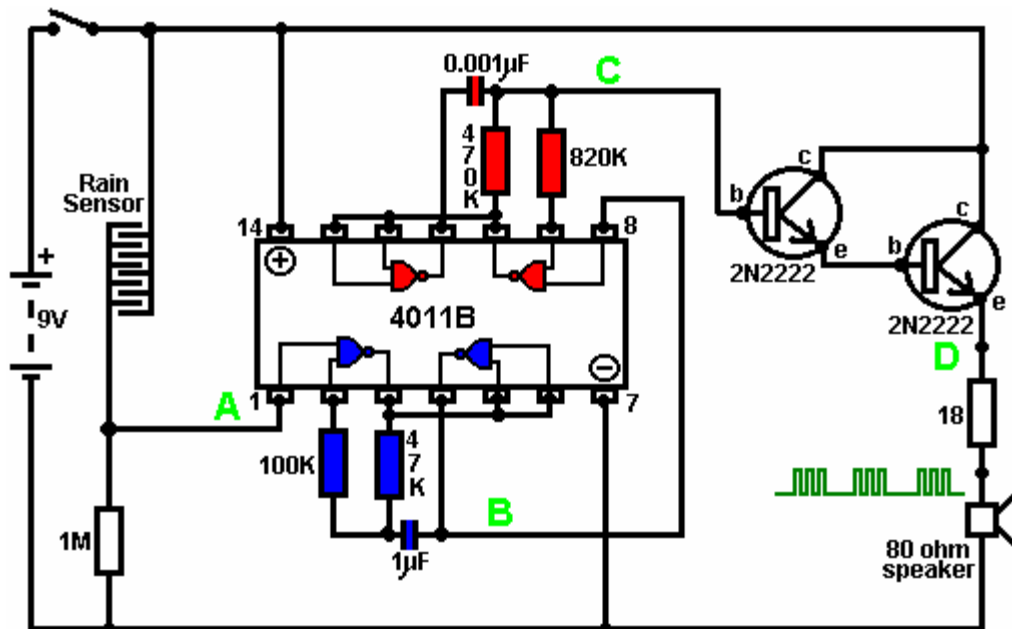

When the ‘Set’ switch is operated, the output of gate ‘2’ is driven high. Now, both inputs of gate ‘1’ are high which causes its output to go low. This in turn, drives one input of gate ‘2’ low, which holds the output of gate ‘2’ high. This is the second stable state.

To summarise: pressing the ‘Set’ switch any number of times, causes the output to go low, once and only once. The output will stay low until the ‘Reset’ switch is operated once, twice or any number of times, at which point the output will go high and stay there.

This circuit uses just half of one cheap NAND gate chip to create a bistable multivibrator which is physically very small and light.

Gate Circuits.

NAND Gates can be used as the heart of many electronic circuits apart from the logic circuits for which the package was designed. Here is a NAND gate version of the rain alarm described earlier. The ‘4011B’ chip is a CMOS device which has a very high input impedance and can operate at convenient battery voltages (3 to 15 Volts):

This circuit is comprised of a rain sensor, two astable multivibrators and a power-driver feeding a loudspeaker:

1. The rain sensor is a wired-up strip board or similar grid of interlaced conductors, forming a voltage-divider across the battery rails.
2. The output voltage from this, at point 'A' in the circuit diagram, is normally low as the strip board is open-circuit when dry. This holds the first NAND gate locked in the OFF state, preventing the first astable from oscillating. This first astable is colour-coded blue in the diagram. Its frequency (the pitch of the note it produces) is governed by the values of the 47K resistor and the 1 microfarad capacitor. Reducing the value of either of these will raise the frequency (note pitch). If rain falls on the sensor, the voltage at point 'A' goes high letting the astable run freely. If the voltage at 'A' does not rise sufficiently when it rains, increase the value of the 1M resistor.
3. The output of the first astable is a low voltage when the sensor is dry. It is taken from point 'B' and passed to the gating input of the second astable, holding it in its OFF state. The speed of the second astable is controlled by the value of the 470K resistor and the 0.001 microfarad capacitor. Reducing the value of either of these will raise the pitch of the note produced by the astable. The rate at which this astable operates is very much higher than the first astable.

When it rains, the voltage at point 'A' rises, letting the first astable oscillate. As it does so, it turns the second astable on and off in a steady rhythmic pattern. This feeds repeated bursts of high speed oscillations from the second astable to point 'C' in the diagram.

4. The Darlington-pair emitter-follower transistors cause the voltage at point 'D' to follow the voltage pattern at point 'C' (but 1.4 Volts lower voltage due to the 0.7 Volts base/emitter voltage drop for each transistor). The high gain of the two transistors ensures that the output of the second oscillator is not loaded unduly. These power-driver transistors place the output voltage across an eighty ohm loudspeaker, padded with a resistor to raise the overall resistance of the combination. The voltage pattern produced is shown at point 'D' and is an attention-grabbing sound.

So, why does this circuit oscillate?:

The circuit will not oscillate if the gating input is low, so assume it to be high. Take the moment when the output of gate 2 is low. For this to happen, the inputs of gate 2 have to be high. As the output of gate 1 is wired directly to the inputs of gate 2, it must be high, and for that to be true, at least one of its inputs must be low. This situation is

shown on the right.

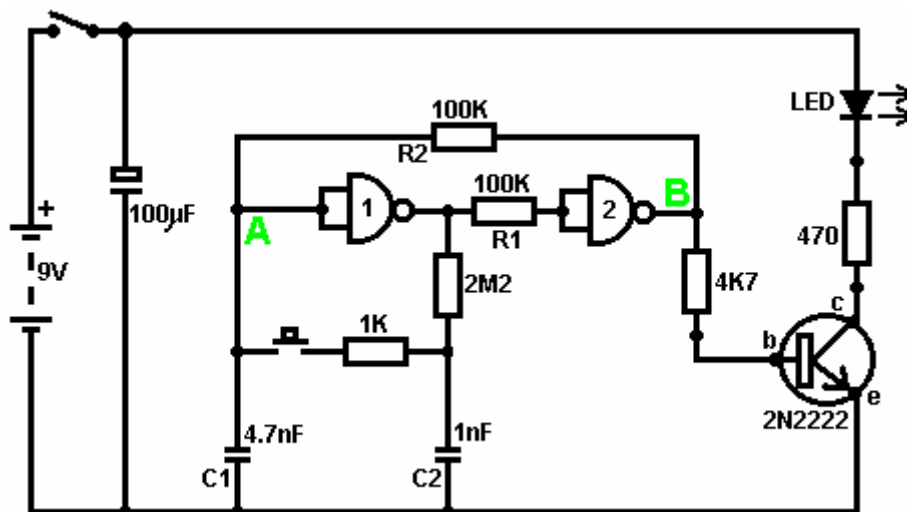

There is now a full voltage drop between point 'A' and point 'B'. The 47K resistor and the capacitor are in series across this voltage drop, so the capacitor starts to charge up, progressively raising the voltage at point 'C'. The lower the value of the resistor, the faster the voltage rises. The larger the value of the capacitor, the slower the voltage rises.

When the voltage at point 'C' rises sufficiently, the 100K resistor raises the input voltage of gate 1 far enough to cause it to change state. This creates the following situation:

Now, the voltage across 'A' to 'B' is reversed and the voltage at point 'C' starts to fall, its rate governed by the size of the 47K resistor and the 1 microfarad capacitor. When the voltage at point 'C' falls low enough, it takes the input of gate 1 low enough (via the 100K resistor) to cause gate 1 to switch state again. This takes the circuit to the initial state discussed. This is why the circuit oscillates continuously until the gating input of gate 1 is taken low to block the oscillation.

Now, here is a NAND gate circuit for a sequential on/off switch:

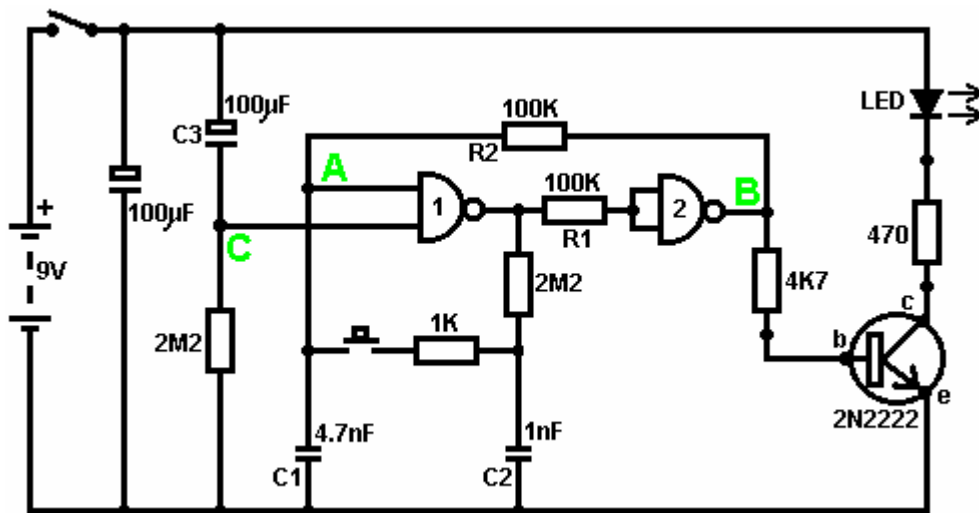

This circuit turns the Light Emitting Diode on and off repeatedly with each operation of the press-button switch. When the on/off switch is closed, capacitor 'C1' holds the voltage at point 'A' low. This drives the output of gate 1 high, which moves the inputs of gate 2 high via the 100K resistor 'R1'. This drives the voltage at point 'B' low, turning the transistor off, which makes the LED stay in its off state. The low voltage at point 'B' is fed back via the 100K resistor 'R2' to point 'A', keeping it low. This is the first stable state.

As the output of gate 1 is high, capacitor 'C2' charges up to that voltage via the 2M2 resistor. If the press-button switch is operated briefly, the high voltage of 'C2' raises the voltage of point 'A', causing gate 1 to change state, and consequently, gate 2 to change state also. Again, the high voltage at point 'B' is fed back to point 'A' via the 100K resistor 'R2', keeping it high, maintaining the situation. This is the second stable state. In this state, point 'B' has a high voltage and this feeds the base of the transistor via the 4.7K resistor, turning it on and lighting the LED.

In this second state, the output of gate 1 is low, so capacitor 'C2' discharges rapidly to a low voltage. If the press-button switch is operated again, the low voltage of 'C2' drives point 'A' low again, causing the circuit to revert to its original stable state.

We could, if we wished, modify the circuit so that it would operate for three or four minutes after switch-on but then stop operating until the circuit was turned off and on again. This is accomplished by gating one of the gates instead of just using both as inverters. If we gated the second gate, then the LED would be left permanently on,

so we will modify the first gate circuit:

This circuit operates exactly the same way as the previous circuit if, and only if, the voltage at point 'C' is high. With the voltage at point 'C' high, gate 1 is free to react to the voltage at point 'A' as before. If the voltage at point 'C' is low, it locks the output of gate 1 at the high level, forcing the output of gate 2 to the low level and holding the LED off.

When the circuit is first powered up, the new 100 microfarad capacitor 'C3' is fully discharged, which pulls the voltage at point 'C' to nearly + 9 Volts. This allows gate 1 to operate freely, and the LED can be toggled on and off as before. As time passes, the charge on capacitor 'C3' builds up, fed by the 2M2 resistor. This causes the voltage at point 'C' to fall steadily. The rate of fall is governed by the size of the capacitor and the size of the resistor. The larger the resistor, the slower the fall. The larger the capacitor, the slower the fall. The values shown are about as large as are practical, due to the current 'leakage' of 'C3'.

After three or four minutes, the voltage at point 'C' gets driven low enough to operate gate 1 and prevent further operation of the circuit. This type of circuit could be part of a competitive game where the contestants have a limited time to complete some task.

The NAND Gate as an Amplifier.

Gates can also be used as amplifiers although they are not intended to be used that way and there are far better integrated circuits from which to build amplifiers. The following circuit shows how this can be done:

This circuit operates when there is a sudden change in light level. The previous light-level switching circuit was designed to trigger at some particular level of increasing or decreasing level of lighting. This is a shadow-detecting circuit which could be used to detect somebody walking past a light in a corridor or some similar situation.

The voltage level at point 'A' takes up some value depending on the light level. We are not particularly interested

in this voltage level since it is blocked from the following circuitry by capacitor 'C1'. Point 'B' does not get a voltage pulse unless there is a sudden change of voltage at point 'A', i.e. there is a sudden change in light level reaching the light-dependent resistor ORP12.

The first gate amplifies this pulse by some fifty times. The gate is effectively abused, and forced to operate as an amplifier by the 10M resistor connecting its output to its input. At switch-on, the output of gate 1 tries to go low. As its voltage drops, it starts to take its own inputs down via the resistor. Pushing the voltage on the inputs down, starts to raise the output voltage, which starts to raise the input voltage, which starts to lower the output voltage, which The result is that both the inputs and the output take up some intermediate voltage (which the chip designers did not intend). This intermediate voltage level is easily upset by an external pulse such as that produced by the ORP12 through capacitor 'C1'. When this pulse arrives, an amplified version of the pulse causes a voltage fluctuation at the output of gate 1.

This voltage change is passed through the diode and variable resistor to the input of gate 2. Gates 2 and 3 are wired together as a makeshift Schmitt trigger in that the output voltage at point 'D' is fed back to point 'C' via a high value resistor. This helps to make their change of state more rapid and decisive. These two gates are used to pass a full change of state to the output stage transistor. The variable resistor is adjusted so that gate 2 is just about to change state and is easily triggered by the pulse from amplifier gate 1. The output is shown as an LED but it can be anything you choose. It could be a relay used to switch on some electrical device, a solenoid used to open a door, a counter to keep track of the number of people using a passageway, etc. etc. Please note that an operational amplifier chip (which will be described later) is a far better choice of IC for a circuit of this type. A gate amplifier is shown here only to show another way that a gate can be utilised.

The NE555 Timer Chip.

There is an exceptionally useful chip designated by the number 555. This chip is designed to be used in oscillator and timer circuits. Its use is so widespread that the chip price is very low for its capability. It can operate with voltages from 5 Volts to 18 Volts and its output can handle 200 mA. It takes 1 mA when its output is low and 10 mA when its output is high. It comes in an 8-pin Dual-In-Line package and there is a 14-pin package version which contains two separate 555 circuits. The pin connections are:

This device can operate as a monostable or astable multivibrator, a Schmitt trigger or an inverting buffer (low current input, high current output).

Here it is wired as a Schmitt trigger, and for variation, it is shown triggering a triac which will then stay on until the circuit is powered down (an SCR could be used just as well with this DC circuit):

And here, a monostable:

And here are two astables, the second of which has fixed, equal mark/space ratio and the first a high output voltage time determined by $R_a + R_b$ and a low voltage output time determined by R_b (2:1 in this case):

Astable Frequencies

	100	470	1K	4.7K	10K	47K	100K	470K	1M
0.1 μF	72,000 Hz	15,319 Hz	7,200 Hz	1,532 Hz	720 Hz	153 Hz	72 Hz	15 Hz	7.2 Hz
0.47 μF	15,319 Hz	3,259 Hz	1,532 Hz	326 Hz	153 Hz	33 Hz	15 Hz	3.3 Hz	1.5 Hz
1.0 μF	7,200 Hz	1,532 Hz	720 Hz	153 Hz	72 Hz	15 Hz	7.2 Hz	1.5 Hz	1.4 secs
2.2 μF	3,272 Hz	696 Hz	327 Hz	70 Hz	33 Hz	7 Hz	3.3 Hz	1.4 secs	3 secs
4.7 μF	1,532 Hz	326 Hz	153 Hz	33 Hz	15 Hz	3.3 Hz	1.5 Hz	3 secs	6.7 secs
10 μF	720 Hz	153 Hz	72 Hz	15 Hz	7.2 Hz	1.5 Hz	1.4 secs	6.7 secs	14 secs
22 μF	327 Hz	70 Hz	33 Hz	7 Hz	3.3 Hz	1.4 secs	3 secs	14 secs	30 secs
47 μF	153 Hz	33 Hz	15 Hz	3.3 Hz	1.5 Hz	3 secs	6.7 secs	30 secs	65 secs
100 μF	72 Hz	15 Hz	7.2 Hz	1.5 Hz	1.4 secs	6.7 secs	14 secs	65 secs	139 secs
220 μF	33 Hz	7 Hz	3.3 Hz	1.4 secs	3 secs	14 secs	30 secs	139 secs	307 secs
470 μF	15 Hz	3.3 Hz	1.5 Hz	3 secs	6.7 secs	30 secs	65 secs	307 secs	614 secs
1,000 μF	7.2 Hz	1.5 Hz	1.4 secs	6.7 secs	14 secs	65 secs	139 secs	614 secs	
2,200 μF	3.3 Hz	1.4 secs	3 secs	14 secs	30 secs	139 secs	307 secs		
4,700 μF	1.5 Hz	3.3 secs	6.7 secs	30 secs	65 secs	307 secs	614 secs		
10,000 μF	1.4 secs	6.7 secs	14 secs	65 secs	139 secs	614 secs			

Note: The high leakage of large value electrolytic capacitors prevents them being used with high value resistors in timing circuits. Instead, use a smaller capacitor and follow the timing circuit with a “divide-by-N” chip to give accurately timed long periods. Not all 555 chips have a manufacturing quality sufficient for them to operate reliably above 20,000 Hz, so for the higher frequencies the chip needs to be selected after testing its actual performance.

We can also wire the 555 to give a variable mark/space ratio while holding the frequency of the oscillation fixed:

The output waveform changes drastically as the variable resistor is adjusted, but the frequency (or pitch of the note) of the output stays unaltered.

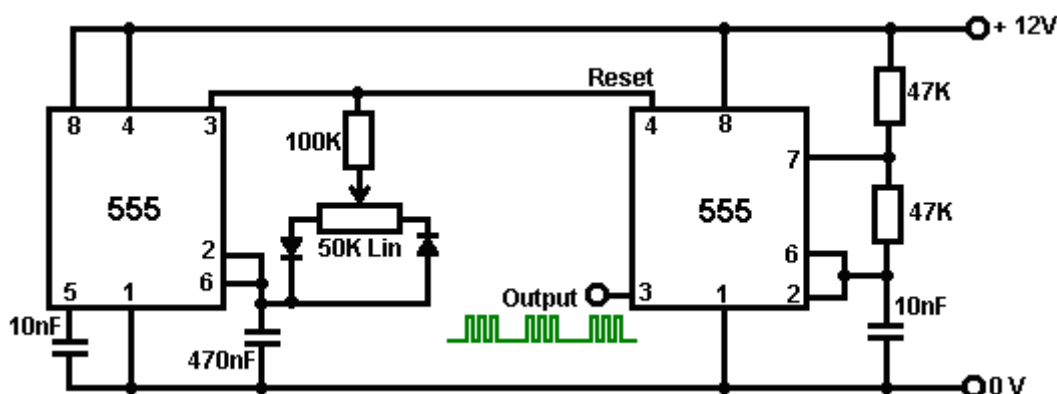

A variable-frequency version of this circuit can be produced by changing the 33K resistor to a variable resistor as shown here:

Here, the 33K resistor has been replaced by two variable resistors and one fixed resistor. The main variable resistor is 47K in size (an almost arbitrary choice) and it feeds to a second variable resistor of 4.7K in size. The advantage of this second variable resistor is that it can be set to its mid point and the frequency tuning done with the 47K variable. When the frequency is approximately correct, the 4.7K variable can be used to fine tune the frequency. This is convenient as the small variable will have ten times more knob movement compared to the main variable (being just 10% of its value).

Obviously, it is not necessary to have the fine-tuning variable resistor, and it can be omitted without changing the operation of the circuit. As the 47K variable resistor can be set to zero resistance and the 4.7K variable resistor can also be set to zero resistance, to avoid a complete short-circuit between output pin 3 and the 50K Mark/Space variable resistor, a 3.3K fixed resistor is included. In this circuit, the frequency is set by your choice of the resistor chain 47K + 4.7K + 3.3K (adjustable from 55K to 3.3K) and the 100nF (0.1 microfarad) capacitor between pin 6 and the zero volt rail. Making the capacitor larger, lowers the frequency range. Making the resistors larger, also lowers the frequency range. Naturally, reducing the size of the capacitor and/or reducing the size of the resistor chain, raises the frequency.

One 555 chip can be used to gate a second 555 chip via its pin 4 'Reset' option. You will recall that we have already developed a circuit to do this using two astables and a transistor. We also generated the same effect using four NAND gates. Here, we will create the same output waveform using the more conventional circuitry of two 555 chips:

Both of the NE555 circuits can be bought in a single 14-pin DIL package which is designated 'NE556':

555 8-pin	555 No.1	555 No.2
2	6	8
3	5	9
4	4	10
5	3	11
6	2	12
7	1	13

There are many additional circuit types which can be created with the 555 chip. If you wish to explore the possibilities, I suggest that you download the free pdf "50 555 Projects" from the web site:

The 555 chip can also produce a sine wave output:

Or, if you wish, a bi-stable multivibrator:

All right, suppose that we want to design and build a circuit to do the same as Bob Beck's pulser circuit mentioned in chapter 11. The requirements are to produce a square wave output pulsing four times per second using a 27 volt power supply, the circuit being powered by three small PP3 size batteries. An obvious choice for the circuit seems to be a 555 timer chip which is small, robust and cheap and a suitable circuit would appear to be:

This leaves us with choosing a value for the capacitor and the resistor. We need to pay attention to the fact that the circuit will be running on 27 volts and while the capacitor will not charge up to anything like that voltage, we still will pick one which will survive 27V. Looking on the local eBay shows that a pack of ten capacitors of 1 microfarad rated at 50V can be bought for just £1 including postage, so take that as the value for "C". Looking at the 555 table of frequencies above shows:

Astable Frequencies

	100	470	1K	4.7K	10K	47K	100K	470K	1M
0.1 μF	72,000 Hz	15,319 Hz	7,200 Hz	1,532 Hz	720 Hz	153 Hz	72 Hz	15 Hz	7.2 Hz
0.47 μF	15,319 Hz	3,259 Hz	1,532 Hz	326 Hz	153 Hz	33 Hz	15 Hz	3.3 Hz	1.5 Hz
1.0 μF	7,200 Hz	1,532 Hz	720 Hz	153 Hz	72 Hz	15 Hz	7.2 Hz	1.5 Hz	1.4 secs

Which indicates that to get the circuit switching four times per second (4 Hz) the resistor "R" will need to be somewhere between 100K and 470K. With my capacitor, 120K is about right.

While the switching frequency does not have to be exact, let's aim at getting it correct. Most reasonably priced components have a tolerance of around 10% so we need to select our resistor/capacitor combination for the exact values of the actual components which we will use. For this, it is worth building the circuit on a solder-less 'breadboard', so looking on eBay again we find that a suitable small plug-in board can be bought and delivered for £3. It looks like this :

These type of boards allow ICs to be plugged in spanning the central divide, leaving up to five extra connections on every pin. Short lengths of solid-core wire can be used to connect between any two socket holes. This will allow us to plug in one of our capacitors and find what resistor (or what two resistors) make the circuit switch forty times in ten seconds.

However, if we go to <http://www.alldatasheet.co.kr/> and download the data pdf for the NE555 chip, we find that the maximum 555 chip voltage is quite limited:

DC AND AC ELECTRICAL CHARACTERISTICS

$T_A = 25^\circ\text{C}$, $V_{CC} = +5\text{V}$ to $+15$ unless otherwise specified.

SYMBOL	PARAMETER	TEST CONDITIONS	SE555			NE555/SE555C			UNIT
			Min	Typ	Max	Min	Typ	Max	
V_{CC}	Supply voltage		4.5		18	4.5		16	V
I_{CC}	Supply current (low state) ¹	$V_{CC}=5\text{V}$, $R_L=\infty$		3	5		3	6	mA
		$V_{CC}=15\text{V}$, $R_L=\infty$		10	12		10	15	mA

This means that the chip is liable to burn out instantly if it is fed more than 16 volts. As we need to run our circuit on 27V this is a problem. As the 27V is being provided by three separate batteries, we could supply the 555 chip from just one of the batteries and run it on 9V which would be ok from the point of view of the chip as the table above shows that it can operate correctly with a supply voltage as low as 4.5 volts. The disadvantage of that arrangement is that one of the batteries will run down more quickly than the others and it would be nice to avoid that.

The table also shows that the current draw just to keep the 555 running can be anything from 6 to 15 milliamps. That is not a large current but the PP3 batteries have been chosen for their small size, allowing the whole circuit to be strapped to a person's wrist. A quick search on the internet shows that cheap PP3 batteries have a capacity of 400 milliamp-hours and the very expensive alkaline types 565 milliamp-hours. These ratings are the "C20" values, based on the battery being discharged at a constant current over a period of twenty hours, which would be ten days of use if Bob Beck's two hours per day protocol is followed.

This means that the 'cheap' batteries should not be discharged at more than one twentieth of their 400 mAHr rating, which is 20 mA. The expensive alkaline batteries should be able to be discharged at 28 mA for twenty hours.

Our current draw is made up of two parts. The first part is supplying the circuit with the current which it needs to run. The second part is the current flowing through the body of the user. This second part is limited by the 820

ohm resistor in the output line which limits that part of the current to a maximum of 33 milliamps (Ohm's Law: Amps = Volts /Resistance). This neglects the body resistance and assumes that the output control variable resistor is set to minimum resistance, which is unlikely.

Checking these values shows that the 555 chip is liable to draw as much current as the circuit supplies through the output electrodes. However, let's go ahead with the circuit, after all, we might decide to use rechargeable PP3 batteries which would overcome the need to buy new batteries every few days.

The first essential requirement is to provide the 555 chip with a voltage of, say, 10 volts when it is running in the completed circuit. That could be done with one of the voltage-stabiliser integrated circuits:

That is not a particularly expensive option, but those chips draw a current in order to provide the voltage stabilisation and an absolutely steady voltage is not needed by the 555 chip. Alternatively, we could use a resistor and a 10V zener diode:

But that method does waste some current flowing through the zener in order to provide the wanted voltage. The most simple method is to use a resistor and a capacitor:

Considerable care is needed when selecting the resistor value "R". If the value is too low, then the voltage passed to the 555 chip will be too high and the chip will burn out. When selecting the resistor "R", start with a higher value than expected and then substitute slightly lower value resistors while monitoring the voltage across the capacitor to make sure that it stays low enough. The resistor value can be assessed using Ohm's Law. Assuming a current of about 6 mA, the voltage drop across the resistor being $(27 - 10) = 17$ volts, then a resistor of about 2.83K (as Ohms = Volts / Amps) which suggests that starting with a 4.7K resistor is likely to be ok, and then picking each lower standard resistor in turn until a satisfactory voltage across the capacitor is reached.

The capacitor could be 12V or 15V rated, but if one rated at a higher voltage is used, then if it is accidentally connected across the full 27V it will not be harmed in any way. The larger the capacitance, the better, say 220 microfarads which can be got for a few pence on eBay. If you want to play safe, you could connect a 12V zener diode across the capacitor. It will not draw any current under normal working conditions, but if anything should cause the voltage on the capacitor to rise, then it will fire up and hold the voltage down to a safe 12V level. I would be inclined to see the zener as being unnecessary, but the choice is always yours.

So what resistor power rating is needed? Well, if the resistor turns out to be a 2.7K and the capacitor voltage ends up as 9.5 volts, then the average voltage across the resistor is 17.5V which makes the current through it 6.48 mA and as Watts = Volts x Amps, the power rating needs to be 113 milliwatts, so the typical quarter-watt (250 mW) resistor should be perfectly ok. If two (nearly equal value) resistors in parallel are used to get some intermediate value of "R" then that increases the overall resistor wattage.

The output of the 555 chip is then used to drive the remainder of the circuit which operates at 27V. A BC109C transistor costs only a few pence, can handle the voltage and has a minimum gain of 200 although the gain can be anything up to 800 and a BC109 can handle the current quite easily. If you need to find out any of these things, then download a datasheet for the transistor from the internet.

The output of the 555 timer is on pin 3 and it can easily supply 200 mA which is far, far more current than we would ever need for this circuit. We can feed the 555 square-wave output to the 27V electrodes using a transistor:

As the transistor is made of silicon, the switch-on voltage is when the base voltage is about 0.7 volts above the emitter voltage. That means that when the transistor is switched on, the top of resistor "R1" will be at around 10 volts and the bottom of "R1" will be at about 0.7 volts, which means that the voltage across "R1" will be $(10 - 0.7) = 9.3$ Volts. When that voltage is present across "R1" we want it to feed sufficient current to the transistor to switch it on fully. The transistor supplies a 100K resistor (which will carry 0.27 mA when 27 volts is across it) and the electrodes which will have a minimum resistance of 820 ohms across them (causing a current of 33 mA through them). So, the transistor might have to supply about 33 mA maximum. The BC109C transistor has a minimum gain of 200 so the current flowing into the base needs to be $33 / 200 = 0.165$ mA and the resistor which will carry that current when it has 9.3 volts across it is 56.3K. A somewhat smaller resistor will suit.

A commonsense check that the resistor calculation is correct is:

A 1K resistor carries 1 mA per volt and so will carry 9.3 mA with 9.3 volts across it.

A 10K resistor will carry one tenth of that amount, or 0.93 mA with 9.3 volts across it.

A 100K resistor will carry one tenth of that again, or 0.093 mA with 9.3 volts across it.

This indicates that for a current of 0.165 mA which is about twice the 100K current, a resistor of about half of 100K should be about the right value, so 56.3K looks correct.

Considering that the gain of 200 is the minimum and three or four times that is typical, we could perhaps choose to use a 47K resistor for "R1"

As the electrode current is likely to be considerably less than 33 mA and as the BC109C gain is likely to be very high, it could be quite difficult to get the transistor to switch off as it can operate on very tiny amounts of input current. To get it to switch on and off cleanly when the 555 output voltage is say, about 5 volts, (at which point the NE555 voltage will be changing very rapidly), "R2" is included. With it in place, the output voltage of the NE555 is divided between "R1" and "R2" in the ratio of their resistances. The situation we want is:

When The transistor is not switched on, it draws almost no current and so looks like a very high value resistor to the circuit. This allows the "R1" and "R2" resistors to act as a voltage-divider pair. This causes the voltage at point "A" to be determined by the ratio of "R1" to "R2" and the transistor can be ignored provided that the voltage at point "A" is below 0.7 volts. If the voltage at that point rises to 0.7 volts then the situation changes dramatically and Ohm's Law no longer holds as the transistor is not a passive resistor but instead, is an active semi-conductor device. If the voltage at point "A" tries to rise further it can't because the transistor base clamps it solidly there by appearing to be an ever lower resistor between the base and the emitter of the transistor. So for higher input voltages, resistor "R2" might as well not be there for all the difference it makes.

So, what value do we need for "R2" in order for the voltage at point "A" to be 0.7V when pin 3 of the NE555 reaches 5V? Well, that part of the circuit is acting in a resistive fashion and so Ohm's Law can be used. The resistor "R1" is 47K and has 4.3 volts across it, which means that the current through it must be 0.915 mA. That means that "R2" has 0.7V across it and 0.915 mA flowing through it which means that it has a value of 7.65K. A standard 8.2K or 6.8K resistor could be used as there is nothing dramatically important about the 5V switching point. If you were fussed about getting exactly 7.65K (and you shouldn't be), then you can get that value by combining two standard resistors, either in series or in parallel.

A common sense method of working out the value of "R2" is to use the fact that as the same current flows through them (no matter what that current happens to be), then the ratio of the voltage will be the same as the ratio of the resistors. That is: $0.7V / 4.3V = "R2" / 47K$ or $"R2" = 47K \times 0.7 / 4.3$ which is 7.65K.

We have now reached the point where we can determine the resistor value needed to provide a reasonable voltage for the NE555 timer chip, the circuit being:

The "Rx" value is going to be fairly close to 270K so you can use that value when testing to find a suitable value for "R" (2.2K in my case). The capacitor across the NE555 chip should be as large a capacitance as is convenient, bearing in mind that the entire circuit, batteries, etc. is to fit into a small case to be strapped to a wrist. One way that the components could be positioned on the plug-board is:

Remember that when trying various resistors for "R" you need to start high at about 4.7K and the resulting voltage on the capacitor shows the voltage drop across your first resistor choice and so, the actual current being drawn by your particular NE555 chip. That calculated current will allow you to calculate the resistor value needed to give 10 volts or so, allowing your next resistor to be tested to be almost exact in value.

For checking the frequency produced by the circuit, any ordinary LED can be used as a temporary measure. It can be connected across the 100K 'load' resistor between the transistor collector and the +27V positive supply

line. A current-limiting resistor is essential to stop the LED burning out instantly. If we allow a current of 5 mA to flow through the LED then since the current-limiting resistor has some 26.3 volts across it, then it's value will be about 5.4K (1K would give 26 mA, 2K would give 13 mA, 3K would give 9 mA, 4K would give 6.5 mA) and so a 4.7K resistor works well. This LED and resistor are shown in the layout above. Please remember that if your BC109C transistor has a metal case, then that case is normally connected internally to the collector and so, care must be taken that the case does not short-circuit to anything else.

If it is considered important to maximise battery life by reducing the current draw to a minimum, then perhaps using an astable circuit might be a good choice. In common with most electronic circuits, there are many different ways to design a suitable circuit to do the required job. The BC109C transistor can handle the 27V and so we might aim at a current draw for the circuit of just 3 mA. If 2 mA were to flow through the astable transistors when they are switched on, then with 27V across them, the resistors would be 13.5K which is not a standard value. We might select 12K to give a 2.25 mA current, or 15K to give 1.8 mA. Either should be satisfactory. The circuit might then be:

As the voltage swing feeding the output transistor has now risen from 10V to 27V the voltage-divider resistors can now increase in value by 2.7 times, giving around 127K and 22.1K for these resistors. However, the situation is not the same as for the NE555 chip which can supply at least 200 mA at the voltage-high output level. Instead, the transistor becomes such a high resistance that it can be ignored, but the 12K remains in the path which supplies the base current for the output transistor and it will in fact, add to the upper resistor of the voltage-divider pair. So while a 100K resistor is shown, it is effectively 112K due to that extra 12K resistor between it and the +27V supply line. The astable transistors will be switching fast at the point where the output transistor changes state, so the output square wave should be good quality. The BC109C transistor can switch on and off a hundred million times per second, so it's performance in this circuit should be very good. A test breadboard layout might be:

We now need to choose the timing components. For an even 50% duty cycle where each transistor is ON for half the time and OFF for half the time, the two timing capacitors can be the same size and then the two timing resistors will have the same value, in my case, 330K but it depends on the actual capacitors used.

Bob Beck's design calls for the LED display to be running when the unit is switched on and then be disconnected when the electrodes are plugged into a 3.5 mm socket mounted on the case containing the circuit. The switched socket looks like this:

When the plug is not inserted into the socket, pin 1 connects to pin 2 and pin 3 is not connected to anything. When the plug is inserted, then pin 1 is isolated, pin 2 is connected to plug pin 4 and pin 3 is connected to plug pin 5.

The Beck circuit is connected to the output socket like this:

This arrangement will give a 27V 4Hz square wave output through the jack socket. But, Bob Beck's original circuit did not do that. Instead, it was like this:

Here, a relay operates two change-over switch contacts which are used to reverse the battery bank contacts four times per second. That is different from just producing a positive-going square wave voltage between the two output terminals. If you were to consider a resistor connected across the output socket, then with the relay switching, the direction of the current reverses four times per second, but with the square wave, while it starts and stops four times per second, the direction of the current is always the same and there is no reversal of direction.

As Bob wanted to avoid using a relay which clicks four times per second all the way through the two-hour treatment described in chapter 11 and in the "Take Back Your Power" pdf on the <http://www.free-energy-info.tuks.nl/> web site, he redesigned the circuit using the very impressive LM358/A integrated circuit:

This chip draws only half of one milliamp, has two very high-gain operational amplifiers and can operate with a wide range of supply voltages. It is also inexpensive.

Bob displays the circuit as:

Bob states that the first section acts as a 4Hz square-wave signal generator, the frequency being controlled by the 2.4M resistor "R1" and the 100nF capacitor "C1". The data sheet for the LM358 states that the output voltage swing is between zero volts and 1.5V less than the supply voltage "Vcc" (which is +27V in this case). That implies that, as would be expected, the pin 1 output voltage from the first stage will switch sharply from 0V to +25.5V and sharply back again, four times per second.

It is difficult to follow the circuit as it is drawn, so it might be a little easier to follow when drawn like this:

The output from the first amplifier inside the LM358 package is on pin 1 and it can supply a large amount of current (if a large current is ever needed). That output goes straight to one of the jack socket connections. It also goes to the pin 6 input of the second amplifier inside the chip and that causes the high-power output of that amplifier on pin 7 to be the opposite of the pin 1 voltage. When pin 1 goes high to +25.5 volts, then pin 7 goes low, to about zero volts. That output is also fed to the other jack socket connection, placing 25.5 volts across the electrodes when they are plugged in to the jack socket.

When the oscillator circuitry connected to the first amplifier causes the voltage on pin 1 to go low, then the output on pin 7 inverts it and so it goes to +25.5 volts. You will notice that while the overall voltage of 25.5 volts is applied again to the jack socket, the polarity is now reversed, achieving what the relay circuit does (although 1.5 volts is lost in the process). This is a neat solution.

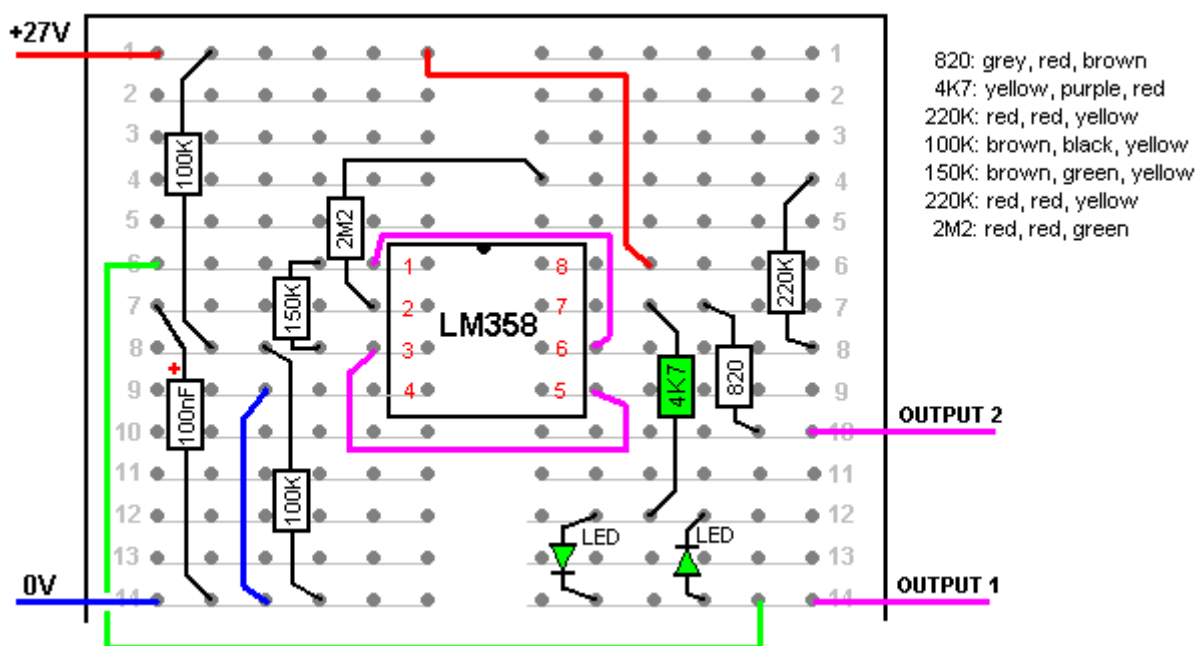

Bob uses a two-colour LED to confirm that the circuit is working correctly before the electrodes are plugged in. He chooses to do it this way:

The two 18V zener diodes drop off 18.7 of the 25.5 volts as one will be forward biased dropping 0.7 volts and the other reversed biased, dropping off 18 volts. That leaves a 7V drop for the LED, which is a bit excessive, so Bob says that he uses a capacitor to limit the current. As there is already an 820 ohm resistor in the LED current path through the socket, the capacitor is not needed. The variable resistor need to be set to it's minimum resistance by rotating it's shaft fully clockwise so that it does not affect the LED brightness as the zeners also show when the battery voltage has dropped as there will no longer be sufficient voltage to light the LED brightly, indicating that the batteries need to be replaced (or recharged if they are rechargeable batteries). When testing the circuit, an alternative to the two zeners is to use a 4.7K resistor and if a bi-colour LED is not to hand, then two ordinary LEDs can be used back to back like this:

With this arrangement, the two LEDs flash alternately. In any circuit, a capacitor with a higher voltage rating can always be used if the capacitance values are the same. The Beck external circuit is completed through the body of the user, so there is just one electrode connected to each side of the output jack socket. A possible plug-board layout is:

The 4.7K resistor and LEDs are only on the board for testing purposes and when the circuit is built in permanent form, then the LED chain connects to pin 1 of the jack socket so that the LEDs are disconnected during the two hours of daily treatment recommended when using the device.

One stripboard layout using the standard 9-strip 25-hole board and incorporating the two 18V zener diodes for voltage sensing is:

When using a Beck device, it is very important to pay attention to the precautions which Bob sets out. These are in his "Take Back Your Power" pdf document: <http://www.free-energy-info.tuks.nl/Beck.pdf> which includes the following, which, while it refers to treatment to deal with HIV, presumably applies to all treatments with his device:

EXPANDED INSTRUCTIONS FOR EXPERIMENTAL / THEORETICAL HIV BLOOD NEUTRALIZATION

HYPOTHETICAL PROTOCOLS FOR EXPERIMENTAL SESSIONS

Revision March 20, 1997. Copyright 8 1991/1997 Robert C. Beck

PRECAUTIONS: Do NOT use wrist to wrist current flow with subjects who have cardiac pacemakers. Any applied electrical signals may Interfere with 'demand' type heart pacers and cause malfunction. Single wrist locations should be acceptable. Do NOT use on pregnant women, while driving or using hazardous machinery.

Users MUST avoid Ingesting anything containing medicinal herbs, foreign or domestic, or potentially toxic medication. nicotine, alcohol, recreational drugs. laxatives, tonics. and certain vitamins etc., for one week before starting because blood electrification can cause electroporation which makes cell membranes pervious to small quantities of normally harmless-chemicals in plasma. The effect Is the same as extreme overdosing which might be lethal. See *Electroporation: a General Phenomenon for Manipulating Cells and Tissues*; J.C. Weaver, Journal of Cellular Biochemistry 51:426-435 (1993). Effects can mimic increasing dosages many fold. Both the magnetic pulsar and blood purifier cause electroporation.

Do NOT place electrode pads over skin lesions, abrasions, new scars, cuts, eruptions, or sunburn. Do NOT advance output amplitude to uncomfortable levels. All subjects will vary. Do NOT fall asleep while using. The magnetic pulser should be safe to use anywhere on body or head.

Avoid ingesting alcohol 24 hours before using. Drink an 8 oz. glass of distilled water 15 minutes before and immediately following each session end drink at least four additional glasses daily for flushing during 'neutralization' and for one week thereafter. This Is imperative. Ignoring this can cause systemic damage from unflushed toxic wastes. When absolutely essential drugs *must* be ingested, do so a few minutes *after* electrification then wait 24 hours before next session.

If subject feels sluggish, faint, dizzy, headachy, light-headed or giddy, nauseous. bloated or has flu-like symptoms or rashes after exposures, reduce pulsing per session and/or shorten applications of electrification. Drink more water-preferably ozonized -to speed waste oxidation and disposal. Use extreme caution when treating patients with impaired kidney or liver function. Start slowly at first like about 20 minutes per day to reduce detoxification problems.

To avoid shock liability, use batteries only. Do NOT use any line-connected power supply, transformer, charger, battery eliminator, etc. with blood clearing device. However line supplies are OK with well-insulated magnetic pulse generators (strobe lights).

Health professionals: Avoid nicotine addicts, vegans, and other unconsciously motivated death-wishers and their covert agendas of 'defeat the healer'. Tobacco, the most addictive (42times more addictive than heroin) and deadly substance of abuse known, disrupts normal cardiovascular function. True vegetarian diets are missing essential amino acids absolutely necessary for the successful rebuilding of AIDS-ravaged tissues. Secondary gains (sympathy / martyrdom, work avoidance, free benefits, financial assistance, etc.) play large roles with many AIDS patients. "Recovery guilt" as friends are dying has even precipitated suicide attempts masked as 'accidents'. Avoid such entanglements, since many have unconscious death wishes.

SUPERIOR ELECTRODES: Excellent, convenient and vastly superior electrodes, reusable indefinitely can be made by butt-soldering lead wires to ends of 1" long by 3/32" dia. blanks cut from type 316 stainless steel rods available from welding supply stores (Cameron Welding Supply, 11061 Dale Ave., Stanton, CA 90680). Use 'Stay Clean' flux before soldering (zinc chloride/hydrochloric acid). Shrink-insulate TWO tight layers of tubing over soldered joints to prevent flexing/breaking and lead/copper ions from migrating. Wrap three or four turns of 100% cotton flannel around rods. Spiral-wrap with strong thread starting from wire side to end, tightly pinch cloth over the rod's end so as to leave no metal exposed by wrapping 6 or 7 turns of thread TIGHTLY just off end of rod, then spiral wrap back to start and tie tightly with four knots then cut off excess cloth at end close to pinch -wraps. Treat end windings and knots with clear fingernail polish or Fray Check® (fabric & sewing supply stores) to prevent ravelling. Soak in a strong solution of sea salt (not table salt) containing a little wetting agent like Kodak Photo Flow, ethylene glycol, or 409 kitchen cleaner. Add a few drops of household bleach, silver colloid, etc., for disinfectant. Store solution for reuse. Tape soaking-wet electrodes tightly over pulse sites with paper masking or Transpore™ tape or with 1" wide stretch elastic bands with tabs of Velcro® at ends to fasten. Electrodes should closely conform *precisely* along blood vessels, not skewing ever so slightly over adjacent flesh. This insures better electrical conductivity paths to circulating blood and insures very low internal impedance. (~2000W). Rinse and blot-dry electrodes and skin after each use. NEVER allow bare metal to touch skin as this will cause burns manifested as small red craters that heal slowly. The objective is to get maximum current into blood vessels, not leak it over to adjacent tissue. Therefore never use any electrode wider than about 1/8 inch (3 mm).

ELECTRODE PLACEMENTS: Locate *maximum* pulse position (*NOT* to be confused with acupuncture, reflexology, Chapman, etc. points) on feet or wrists by feeling for maximum pulse on inside of ankle ~1" below and to rear of ankle bone, then test along top centre of instep. Place electrode on whichever pulse site on that foot that feels strongest. Scrub skin over chosen sites with mild soap and water or alcohol swab. Wipe dry. Position the electrodes lengthwise along each left and right wrists blood vessel. Note: with subjects having perfectly healthy hearts and not wearing pacers, it is convenient to use left wrist to right wrist exactly over ulnar arterial pulse paths instead of on feet. Recent (Dec. 1995) research suggests that placing both electrodes over different arteries on the same wrist works very well (see pg. 7), avoids any current through heart, and is much more convenient and just as effective. An 8" long, 1" wide elastic stretch-band with two 1.5" lengths of 3/4" wide Velcro® sewn to ends of opposite sides makes an excellent wrist band for holding electrodes snugly in place. With electrode cable unplugged, turn switch ON and advance amplitude control to *maximum*. Push momentary SW. 2 'Test' switch and see that the red and green light emitting diodes flash alternately. This verifies that polarity is reversing about 4 times per second (frequency is *NOT* critical) and that batteries are still good. When LED's don't light replace all three 9V batteries. Zener diodes will extinguish the LEDs when the three 9V battery's initial 27V drops below 18V after extended use. Never use any electrode larger than 1.125" (28 mm) long by 1/8" wide to avoid wasting current through surrounding tissue. Confine exactly over blood vessels only. Apply drops of salt water to each electrode's cotton cover ~every 20 minutes to combat evaporation and insure optimum current flow. Later devices are solid-state, use only three batteries and no relays, and are much smaller.

Now rotate amplitude control to *minimum* (counter-clockwise) and plug in electrode cable. Subject now advances dial slowly until he feels a "thumping" and tingling. Turn as high as tolerable but don't advance amplitude to where it is ever uncomfortable. Adjust voltage periodically as he adapts or acclimates to current level after several minutes. If subject perspires, skin resistance may decrease because of moisture, so setting to a lower voltage for comfort is indicated. Otherwise it is normal to feel progressively less sensation with time. You may notice little or no sensation at full amplitude immediately, but feeling will begin building up to maximum after several minutes at which time amplitude must be decreased. Typical adapted electrode-to-electrode impedance is on the order of 2000W. Typical comfortable input (to skin) is ~3mA, and maximum tolerable input (full amplitude) is ~7mA but this 'reserve' margin although harmless is unnecessary and can be uncomfortable. Current flowing through blood is very much lower than this *external* input because of series resistance through skin, tissue and blood vessel walls, but 50 to 100 µA through blood is essential.

Apply blood neutralizer for about 2 hours daily for ~2 months. Use judgment here. The limiting factor is detoxification. Carefully monitor subject's reactions (discomfort, catarrh, skin eruptions, weeping exudates, rashes,

boils, carbuncles, coated tongue, etc.). With very heavy infections, go slower so as not to overload body's toxic disposal capability. With circulation-impaired diabetics, etc., you may wish to *extend* session times. Again, **have subject drink lots of water.** Recent changes in theoretical protocol being currently tested suggest following up the three weeks of treatments with a 24 hours per day (around the clock) continuous electrification of blood for two days to deal a knockout blow to the remaining HIV's 1.2 day life cycle. (A. Perelson; Los Alamos Biophysics Group, Mar. 16, 1996 "Science" Journal.) Remember to remoisten electrodes regularly. If you absolutely **must** ingest prescription drugs, do so immediately **after** turning off instrument and allow 24 hours before next treatment to let concentrations in blood plasma decay to lower levels.

Remember, if subjects ever feel sleepy, sluggish, listless, nauseous, faint, bloated, or headachy, or have flu-like reactions they may be neglecting sufficient water intake for flushing toxins. We interpret this as detoxification plus endorphin release due to electrification. Let them rest and stabilize for about 45 minutes before driving if indicated. If this detoxing becomes oppressive, treat every *second* day. Treating at least 21 times should 'fractionate' both juvenile and maturing HIV to overlap maximum neutralization sensitivity windows and interrupt 'budding' occurring during HIV cells' development cycles. Treatments are claimed to safely neutralize many other viruses, fungi, bacteria, parasites, and microbes in blood. See patents US 5,091,152 US 5,139,684 US 5,188,738 US 5,328,451 and others as well as numerous valid medical studies which are presently little known or suppressed. Also, ingesting a few oz. of about 5 parts per million of silver colloid solution daily can give subjects a 'second intact immune system' and minimise or eliminate opportunistic infections during recovery phase. This miracle substance is pre-1938 technology, and unlike ozone is considered immune from FDA harassment. Silver colloid can *easily* be made at home electrolytically in minutes and in any desired quantities and parts per million strength for under 14 cents per gallon plus cost of water. It is ridiculous to purchase it for high prices. Colloid has no side effects, and is known to rapidly eliminate or prevent hundreds of diseases. Silver colloids won't produce drug resistant strains as will all other known antibiotics. No reasonable amount can overdose or injure users either topically, by ingestion, or medical professional injection.

The 741 Operational Amplifier.

An important and very useful group of Integrated Circuits is the "Operational Amplifier" or "op-amp" group. These devices have a very high gain, an 'inverting' input and a 'non-inverting' input. There are many op-amps but we will look at just one popular type called the "741" which has an 'open-loop' gain of 100,000 times. All operational amplifiers work in the same way in theory. The way they operate in a circuit is controlled by the external components attached to them. They can operate as inverting amplifier, a non-inverting amplifier (i.e. a 'buffer'), a comparator, an astable multivibrator, and various other things. The symbol and connections for a 741 op-amp are:

We can connect the 741 chip to act as an amplifier with any set gain level that we choose:

Here, the gain is set by the ratio of the 220K resistor to the 22K resistor. This circuit has a gain of 10 times, so the input signal at point 'B' will generate an output signal at point 'C' which is ten times larger, **provided** that the output signal does not approach the battery voltage. If it does, then clipping will occur with the top and the bottom of the output waveform chopped off at about a volt away from the battery voltage levels, approximately 1 Volt and +11 Volts in this example.

Operational amplifiers are generally designed to operate from a dual power supply. In the above example, the supply would be created by using two 6 Volts batteries instead of one 12 Volt battery. To avoid the inconvenience of this, a mid-point voltage is generated at point 'A' by using two equal resistors in series across the battery. This gives a central voltage of +6 Volts which is fed to the IC.

This circuit can be used in many applications. Here is a circuit for a meter to measure sound intensity:

This circuit is two copies of the previous circuit. Each 741 chip has a reference voltage of half the supply voltage created by a voltage-divider pair of 1K resistors. This voltage is fed to pin 3 of the chip, which is the non-inverting input.

At point 'A', a microphone or small loudspeaker is used to generate a signal voltage when sound reaches it. This voltage is fed to the 741 op-amp via a 1 microfarad blocking capacitor. This passes the audio signal through while blocking the +4.5 Volts DC on pin 3. The first 741 has a gain of 22, set by the 10K and 220K resistors ($220/10 = 22$).

Point 'B' then receives an audio signal 22 times larger than the signal produced by the microphone. This signal is still quite small, so the second 741 boosts it further. The gain of the second 741 is variable and depends on the resistance set on the 1M variable resistor. If the variable resistor is set to zero ohms, then the gain of the second 741 will be controlled by the 4K7 resistor at point 'C' alone and so will be 1 ($4.7/4.7 = 1$). If the variable resistor is set to its maximum value, then the gain of the second 741 will be some 214 ($1,004,700/4,700 = 213.8$).

The two op-amps together have a combined gain which ranges from 22 to 4702. The amplified audio signal arrives at point 'D' and it can be adjusted to a respectable value. This alternating voltage is now rectified via the diodes at point 'E' and it builds up a DC voltage across the 47 microfarad capacitor there. This voltage is displayed on a voltmeter. The result is that the voltmeter shows a reading directly proportional to the sound level reaching the microphone.

The 741 can be wired as a **buffer**. This is the equivalent of an emitter-follower circuit when using transistors. The set up for the 741 is:

Difficult circuit - huh! Are you sure you can afford all the extra components? This circuit utilises the full gain of the 741 chip. The output follows the input waveform exactly. The input requires almost no current, so the circuit is described as having a 'high input impedance'. The output can drive a serious load such as a relay, so the circuit is described as having a 'low output impedance'.

The 741 chip can be wired to act as a comparator. This is the circuit:

Are you sure you are up to such a difficult circuit? Bit complicated - huh! This is the basic operational form for an operational amplifier.

If the voltage at point 'A' is higher than the voltage at point 'B' then the output goes as low as it can go, say 1 or 2 volts.

If the voltage at point 'A' is lower than the voltage at point 'B' then the output goes as high as it can go, say 10 volts or so.

Having seen how transistor circuits work, you should be able to understand why the 741 chip circuitry (which is a transistor circuit inside the 741 package) needs some voltage inside the supply rails to provide an efficient high-current output drive.

Here is a 741 version of the light-operated switch:

This circuit is set up as evening falls. We want the relay to have minimum voltage across it in daylight, so the voltage at point 'A' needs to be higher than the voltage at point 'B'. As the 1K variable resistor is across the supply voltage, its slider can be set to any voltage between 0 Volts and +12 Volts. To make this easy to do, we choose a 'linear' variable resistor as the logarithmic variety would be hard to adjust in this application. With the 'linear' version, each 1 degree of rotation of the resistor shaft causes the same change in resistance, anywhere along the range. This is not the case for the logarithmic variety.

Anyhow, we adjust the variable resistor downwards until the relay voltage drops to a minimum. When the light level has fallen to the level at which we wish the circuit to trigger, we adjust the variable resistor to make the relay click on. The 741 chip has a very rapid output voltage swing when the input voltages swap over, so the relay switching will be decisive. The switching can be made even more positive by adding a resistor between the output and point 'B'. This acts like a Schmitt trigger when switching occurs by providing some additional positive feedback, lifting the voltage at point 'B'.

If you wish the circuit to trigger on a rising light level, just swap the positions of the 10K resistor and the ORP12 light-dependent resistor. The same circuit will operate as a temperature sensing circuit by substituting a 'thermistor' (which is a temperature-dependent resistor) for the ORP12.

If we would like the circuit to act as a burglar alarm, we could use the same circuit like this:

The circuit is still controlled by the voltage at point 'A'. Under normal circumstances, this voltage will be near +6 Volts (produced by the two 10K resistors and the 100K resistor). The upper switch marked 'NC' for 'Normally Closed', represents a chain of, say, magnetic switches attached to doors and windows. If any of these are opened, then the voltage at point 'A' will be dictated by the lower 10K resistor in series with the 100K resistor. This will cause the voltage at 'A' to fall instantly to a low value, triggering the circuit.

The 'NO' switch ('Normally Open') represents one or more pressure-operated switches under carpets or rugs and/or switches which get brushed when doors are swung open, etc. These switches are wired in parallel across each other and if any of them is closed for even a millionth of a second, the voltage at point 'A' will be pulled down by the 1K resistor and the circuit will be triggered.

The circuit can be latched on in any one of a variety of ways. One relay contact can be used to hold the relay on or hold the voltage at 'A' low. A transistor can be wired across the relay to hold the circuit on, etc. etc. If this is done, the circuit will remain in its triggered state until the supply voltage is interrupted. You might prefer to use a 555 chip to limit the length of time the alarm sounds to three minutes or so.

The SCR and Triac.

An alternative to using a relay or semiconductor latch is to use a **Silicon Controlled Rectifier** usually referred to as an 'SCR' or 'Thyristor'. This device is normally "off" with a very high resistance to current flow. If it is switched on by applying a voltage to its Gate connection, it stays continuously on until some external device stops current flowing through it. The following circuit shows how it operates:

When the voltage is first applied to the circuit by closing switch S2, the SCR is in its OFF state so no current is supplied to the load. If the press-button switch S1 is pressed, a current is fed into the Gate of the SCR, turning it ON. When switch S1 is allowed to open, the SCR remains in its ON state and it will stay that way until the current through it is cut off. Opening switch S2 cuts off the current to the load and the SCR returns to its OFF state. A very valid question would be: "Why have an SCR at all and just turn the load on and off with switch S2?". The answer is that switch S1 might be the under-carpet pressure pad of a burglar-alarm and it might be operated some hours after switch S2 was closed to activate the alarm system. Stepping off the pressure pad does not stop the alarm sounding.

While this sort of DC latching action is useful, it is more common for an SCR to be used in an AC circuit. For example, take the circuit shown here:

The 120 volt AC supply coming in from the right hand side, is converted to positive-going sine-wave pulses by the diode bridge. This pulsing voltage is applied to the Load/SCR path. If the voltage at pin 3 of the 555 chip is low, then the SCR will remain OFF and no current will be fed to the load device. If the voltage on pin 3 goes high **and** the voltage applied to the Load/SCR chain is high, then the SCR will be switched ON, powering the load until the pulsing voltage drops to its zero level again some 1/120 of a second later.

The 555 chip is connected to form a monostable multivibrator and the timing components (the 120K resistor and the 10nF capacitor) cause it to output a 1 millisecond pulse which is long enough to trigger the SCR into its ON state, but short enough to have finished before the mains pulse reaches its zero-voltage level again. The 555 chip is triggered by the rising mains voltage being passed to its pin 2 through the voltage-divider 100K and 120K pair of resistors, and that synchronises it with the AC waveform. Pin 4 of the 555 chip can be used to switch the load power on and off.

In the circuit shown above, the diode bridge is needed to convert the incoming AC waveform to pulsing DC as shown in red in the diagram, as the SCR can only handle current flowing in one direction. The AC load equipment works just as well with the pulsing DC as with a full blown AC waveform. A better semiconductor construction is the 'Triac' which acts like two SCR devices back-to-back in a single package. It is shown like this in circuit diagrams:

There are three connections to the device: Main Terminal 1, Main Terminal 2 and the Gate. When switch 'S' shown in the diagram is closed, the triac conducts on both positive and negative voltages applied to its MT1 and MT2 terminals. When the switch is open, the device does not conduct at all.

If the external circuit containing switch 'S' is placed inside the device as a permanently closed circuit, then the device becomes a 'Diac' which can be used to trigger a Triac and give a very neat circuit for controlling the power to an item of AC mains equipment as shown here:

Here, the variable resistor/capacitor pair controls the point on the AC waveform that the Triac is triggered and so controls how much of each sinewave cycle is passed to the mains equipment, and so it controls the average power passed to the equipment. A very common use for a circuit of this type is the 'dimmer-switch' used with household lighting.

To return now to the 741 chip. The 741 can also be used as an **astable multivibrator**. The circuit is:

The rate of oscillation of this circuit is governed by the Resistor marked 'R' in the diagram and the capacitor marked 'C'. The larger the resistor, the lower the rate of oscillation, the larger the capacitor, the lower the rate of oscillation.

When the output goes high, capacitor 'C' charges up until the voltage on it exceeds the mid-rail voltage on pin 3, at which time the 741 output goes low. The capacitor now discharges through resistor 'R' until the voltage on it drops below the voltage on pin 3, at which time the output goes high again. The 10K resistor connecting the output to pin 3 provides some positive feedback which makes the 741 act quite like a Schmitt trigger, sharpening up the switching.

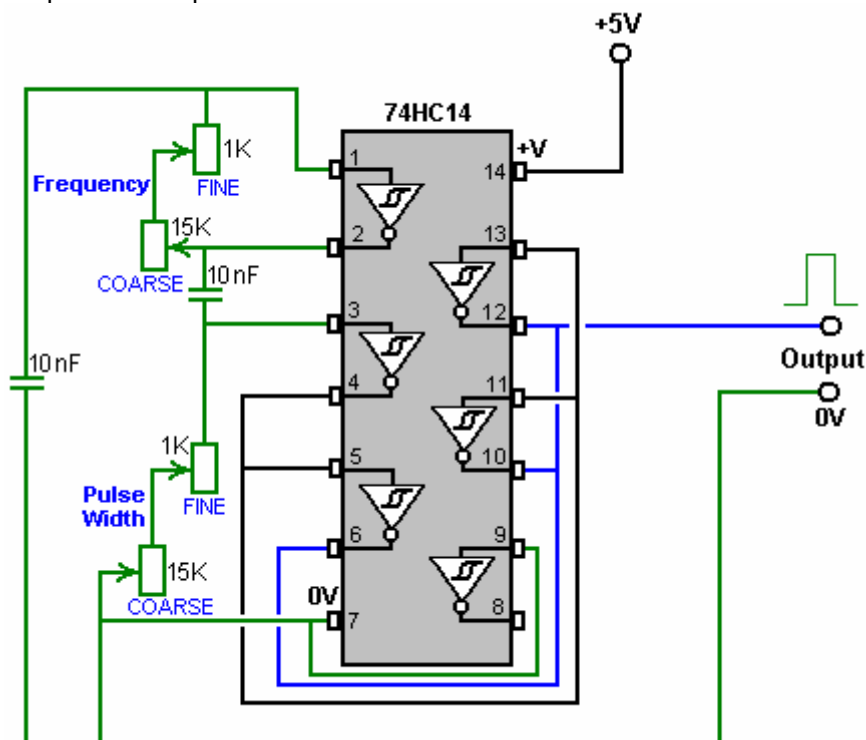

The same arrangement of resistor and capacitor applied to a Schmitt inverter or Schmitt NAND gate causes exactly the same oscillation:

If you would like to see additional ways of using 741 and 555 chips, I can recommend the excellent book "Elementary Electronics" by Mel Sladdin and Alan Johnson ISBN 0 340 51373 X.

A Hex Inverter Signal Generator.

Here is a very well tested and highly thought of, low-cost oscillator circuit, using a 74HC14 Schmitt inverter chip. It allows fine tuning control of the frequency and the pulse width produced. Three of the inverters are connected together to give a more powerful output current drive:

The 4022 Divide-by-Eight Chip.

One very useful CMOS integrated circuit is the '4022' chip which is a 16-pin 'divide by 8' chip with built-in decoding. The connections are:

If pin 14 is provided with the output from some variety of astable multivibrator, on the first pulse, this chip sets the "0" output on pin 2 to High while the other outputs are Low. On the next pulse, the "0" output goes Low and the "1" output on pin 1 goes High. On the next pulse, output "1" goes Low and the "2" output on pin 3, goes High. And so on until on the eighth pulse, output "7" on pin 10 goes Low and output "0" goes high again.

The chip can also divide by lower numbers:

For 'Divide by 7' operation, connect pin 10 to pin 15 (this resets the output to '0')

For 'Divide by 6' operation, connect pin 5 to pin 15

For 'Divide by 5' operation, connect pin 4 to pin 15

For 'Divide by 4' operation, connect pin 11 to pin 15

For 'Divide by 3' operation, connect pin 7 to pin 15

For 'Divide by 2' operation, connect pin 3 to pin 15

If you want a 'Divide by 1' circuit, I suggest you cut down on the amount of alcohol you drink.

Here is an illustration of a 'Divide by 4' setup:

There are a number of things to notice in the above diagram. Firstly, the practical arrangements for circuitry have not been stressed before. If the circuitry has a pulsing circuit drawing heavy current, as shown by the thick red arrows, then it should be physically connected to the battery and any low-current circuitry should be further away from the battery. The supply from the battery should have a fuse or circuit breaker and a switch in the line before anything else is connected, so that if any component develops a fault and goes short-circuit, the fuse will blow and prevent any significant problems.

Secondly, it is a good idea to provide the other circuitry with a smoothed power supply as shown by the blue components in the diagram. This minimises the effect if the battery voltage gets pulled down by the pulsing of the

high-current circuitry. The diode (silicon, 1 Amp, 50 V) stops the heavy current circuit drawing current from the large smoothing capacitor. The 100 ohm resistor limits the current into the large capacitor on switch-on and provides a little more smoothing. This circuitry is called “de-coupling” as it de-couples the low current circuitry from the high current circuitry.

Thirdly, notice capacitor “C1” which is wired physically as close to the power supply pins of the integrated circuit as is possible. If a spike is superimposed on the battery supply, then this capacitor soaks it up and prevents it damaging or triggering the integrated circuit. A spike could be caused by a very strong magnetic pulse nearby as that can induce an extra voltage in the battery wires.

The lower part of the diagram shows the output voltages produced as the clock pulses reach pin 14 of the chip. The positive-going part of the clock signal triggers the change in state of the outputs. If necessary, a positive-going pulse on the reset pin, pin 15, causes output “0” to go high and the other outputs to go low.

The 4017 Divide-by-Ten Chip.

Now, to take this output sequencing a little further. For example, the Charles Flynn magnet motor shown in Chapter 1 needs coils to be powered up, one after the other and only one should be on at any one time. This calls for a circuit which has a large number of outputs. The CD4022BC chip gives up to eight outputs one after the other. The CD4017B chip gives up to ten outputs one after the other but there is no need to be limited by these numbers as more than one chip can be used. If you find this section difficult to understand, then just skip past to the next section as it is not important for you to understand these larger circuits.

The pin connections for the divide-by-ten CD4017B chip is shown here:

While this shows outputs 1 to 10, the manufacturers and some people who draw circuits, prefer to label the outputs as “0 to 9” which correspond to digital displays. In our style of operation, it is easier to think of the ten outputs as being from 1 to 10.

You will notice that there are two pin labels which we have not come across before, namely, the “Carry-out” pin and the “Clock Enable” pin. These allow us to use several of these chips in a row to give a much larger “divide-by” number. The “Clock Enable” pin can be used to block the clock input. The operation is like this:

In this example, the sequence is started by the Reset pin being given a high voltage as shown by the green shading. This pushes the output pin 1 to a high voltage and all of the other outputs to a low voltage and holds those voltages as long as the reset voltage is high.

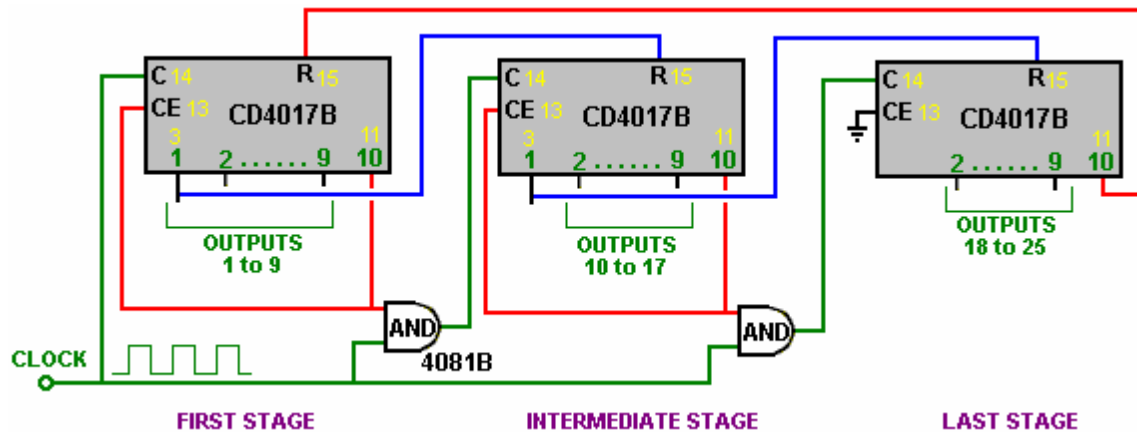

When the Reset voltage drops, the next rising edge of the clock pulse (marked "1" in the diagram) causes the output 1 to go low and output 2 to go high. Each of the successive clock pulses "2" to "9" moves the high voltage steadily along the outputs until output pin 10 is high.

The next clock pulse rising edge (marked "10" in the diagram) starts the sequence again with output 10 going low and output 1 going high again. If nothing changes, then that sequence of output voltage changes will continue indefinitely.

However, in the diagram above, the Clock Enable pin voltage is driven high on clock pulse "11". Output 2 has just gone high and would have gone low when the rising edge of clock pulse "12" occurred, but in this case, the Clock Enable feature blocks the clock pulse and prevents it reaching the rest of the circuitry. This causes the output 2 voltage to stay high as long as the Clock Enable remains high. In this example, the Clock Enable voltage stays high for just one clock pulse, causing the output 2 voltage to be high for twice its usual length, and then the sequence continues as before.

A Divide-by-Twenty-five Circuit.

Here is one way to get a large "divide-by" number. This example is divide-by-25 because there is only one 'intermediate stage' but there can be any number and each additional one adds another eight outputs to the total:

At startup, output 10 of the first stage (which is physical pin 11 of the chip) is at a low voltage. This holds the Clock Enable (pin 13) low, allowing the clock pulses to enter the first stage. Because the output 10 voltage is low, one input to the first AND gate is held low, preventing it from letting the clock pulse flow through it, i.e. the "gate" is closed to through traffic.

The first stage chip then operates as normal, producing outputs 1 to 9 in order as you would expect. The next clock pulse steers the first stage output 10 high, allowing the clock pulses through the first AND gate and holding the Clock Enable (pin 13) high, which in turn locks the output 10 high, dropping the first stage chip out of the operation.

As the output 1 of the first stage is connected to the Reset (pin 15) of the second chip, it will have been cleared and its output 1 set high, which in turn Resets the third chip and closes the second AND gate. So, when the first pulse gets through to the second chip, it pushes it from state 1 to state 2 where the output 2 goes high. For that reason, output 1 of the second chip is not one of the outputs which can be used by whatever following circuitry you choose to connect to this system. Consequently, only eight of the ten outputs of the second chip are available as counter outputs. That is, outputs 1 and 10 are taken up in passing the switching sequence between the various chips in the chain.

The same applies to all following chips in the chain, each extra chip adding up to eight extra sequential outputs. On the final stage chip, if you connect the red Reset wire (which goes back to fire up the first chip again) to output 9 instead of output 10 of the final chip, then you get a divide-by-24 result.

If the Reset is taken from output 8 of the final chip, then you get a divide-by-23 result, and so on. Using this method, you can have a divide-by circuit for any number you want. These chips are very popular and so their cost is low, making the entire circuit cheap to make. The pin connections for the AND gates is shown here:

The PIC Revolution.

Over the years, there have been advances in the way that circuitry can be put together, prototypes built and tested. Initially, "valves" or "vacuum tubes" were used and circuits required a good deal of electrical power in order to operate. Mechanical vibrators or "reeds" were used to generate the switching needed to convert DC into AC. Then the transistor became widely available and the transistor replaced the mechanical vibrator reed, the circuit being called an "astable multivibrator" and comprising of two transistors wired back to back (as described in chapter 12). Then came the digital integrated circuit with its "NOR gates" which could also be wired back to back to make a multivibrator. This was done so often that a special integrated circuit called the "555 chip" was designed to do the job all on its own. That chip has been a tremendous success and is now found in all sorts of different circuits, being very easy to use, very robust and very cheap. Surprisingly, the dominant position of the "555" chip is being challenged by a completely different type of chip, one which is essentially, a computer on a

single chip, and which is called a "PIC controller".

This new type of chip is not expensive, is easy to use, and can be changed to perform a different task in just a few seconds. It can perform timing tasks. It can act as a multivibrator. It can act as a "Divide-by-N" chip. It is a very impressive chip which is very useful. The reason that I mention it here is because it is at the heart of the fastest working Tesla Switch research forum around (the "energetic forum" group). The chip is something you need to know about as it will certainly take over more and more circuit applications in the coming years.

There is a whole family of these processor chips, but I will select just one for this description, and that will be the one being used by the "energetic forum" members, and I have to thank Jeff Wilson for his help in describing this circuitry, the programming and the methods which he uses.

First, however, some information on this new design of chip and the methods used with it. The one used by Jeff is called the "PICAXE-18X" and it looks like the chip shown here. From which you can see, it looks just like any other chip, although with eighteen pins. The powerful performance comes from the way that it operates. You are probably familiar with the "555" chip and understand that it operates by changing the voltage on just one of its pins (pin 3) the output pin, from a low voltage to a high voltage. The PIC chip can do that as well, but even better still, it has more than one output pin and it can alter the voltage on any of those pins to either a high or a low voltage and it can do that in any order and with any timing that you choose. This makes it a very versatile chip indeed and one which is very well suited to be the central controller for a Tesla Switch test environment.

The chip is used by wiring it into a circuit in the same sort of way that a 555 chip would be used, except that the PIC has its own internal timing clock and can operate in intervals of one thousandth of a second, that is, one millisecond.

PICAXE-18X

The top eight pins are for making the chip work. The next two are for providing the chip with electrical power. The bottom eight pins are separate outputs, any one of which can operate switches, timers, etc., just as the output from a 555 chip can. Having been named by computer people, instead of the eight output pins being numbered from 1 to 8 as any rational person would do, they have numbered them from 0 to 7.

The voltage on those output pins will be either High or Low. PIC switching can be used with a wide range of different free-energy designs. The PIC chip is generally supplied with a socket, a connecting cable and a program for feeding instructions into the chip. The feed is generally from an ordinary PC. The programming instructions are very simple and anyone can learn how to use them in just a few minutes.

So let's look at a circuit which has been used by Jeff when he tests prototype circuitry. The first part of the circuit is for connecting the standard PC socket to the PIC chip and it looks like this:

A standard 9-pin computer socket has its pin 2 connected to the PIC's pin 2, pin 3 connected to the PIC's pin 3 via a 10K / 22K voltage divider resistor pair (which lowers the incoming signal voltage), and pin 5 is connected to the PIC's pin 5. That is all that's needed to feed information into the PIC chip.

The chip is supplied from a 12-volt battery but as it needs a 5-volt supply, the 100 / 150 ohm (2 watt) resistor pair is used to drop the 12 volts down to about 7 volts and then the 5.1-volt zener diode clamps the voltage at 5.1 volts, which is just what the chip needs. The tiny 10 nF (0.01 microfarad) capacitor is there to trap any voltage spikes should any be picked up from some outside influence. Finally, the press-button switch used to short between pins 4 and 5 is used to wipe out the program inside the PIC, ready for a new program to be loaded.

The actual programming is not difficult and the feed into the chip is handled by the program supplied with the chip and which is run on your home computer. Let's take an example. Suppose we want the output on pin 10 to act as a clock signal. The people who made the chip expect that pin to be called "Output 4" in the program. Please don't ask me why it isn't called "10" in the program as I have no answer for you other than "it takes all sorts of people to make a world".

All right, suppose we want to produce an output signal like a 555 chip running at 50 Hz. We choose one of our output pins, say, the physical pin 10, that being the bottom right hand pin on the chip. As you can see from the pin diagram of the chip shown above, pin 10 is called "Output 4" in a set of commands, or just "4" to save typing. The program might be:

```
Main:
  high 4
  pause 10
  low 4
  pause 10
goto Main
```

Wow - really difficult stuff !! Only a genius could manage to program! Well, we'll see if we can struggle along with this "difficult" stuff.

The "Main:" at the start is a "label" which can be jumped to and that is done by the "goto Main" command which sends the chip back to repeat the commands in the loop indefinitely (or until the chip is powered down).

The second line "high 4" tells the chip to put the maximum possible voltage on the "Output 4" which is the physical pin 10 of the chip. The chip does this immediately, with no time delay.

If we want the output to give a 50 Hz output signal, then the voltage on our chosen output pin will have to go high, pause, go low, pause and go high again, 50 times each second. As there are 1,000 milliseconds in one second, and the chip's clock runs with 1 millisecond ticks, then we need our complete cycle of "up, pause, down, pause" to happen 50 times in those 1,000 clock ticks. That is, once every 20 ticks, so each delay will be 10 clock ticks long.

The third line "pause 10" tells the chip to sit on its hands and do nothing for the next 10 ticks of its internal clock (which ticks 1,000 times per second).

The fourth line "low 4" tells the chip to lower the output voltage on its "Output 4" (pin 10 in real life) to its minimum value.

The fifth line "pause 10" tells the chip to wait for 10 milliseconds before doing anything else.

The last line "goto Main" tells the computer to go back to the label "Main:" and continue with whatever instructions follow that label. This puts the chip into an 'infinite loop' which will make it generate that output waveform continuously. The output will look like this:

This gives an even waveform, that is, one with a Mark/Space ratio of 50:50 or a Duty Cycle of 50%. If we want the same rate of pulsing but a Duty Cycle of just 25% then the program would be:

```
Main:
  high 4
  pause 5
  low 4
  pause 15
goto Main
```

which produces this waveform:

If you wanted "Output 7" (physical pin 13) to do the reverse of this at the same time - that is, when Output 4 goes high we want Output 7 to go low, and vice versa, then, for a 20% Duty Cycle the program would be:

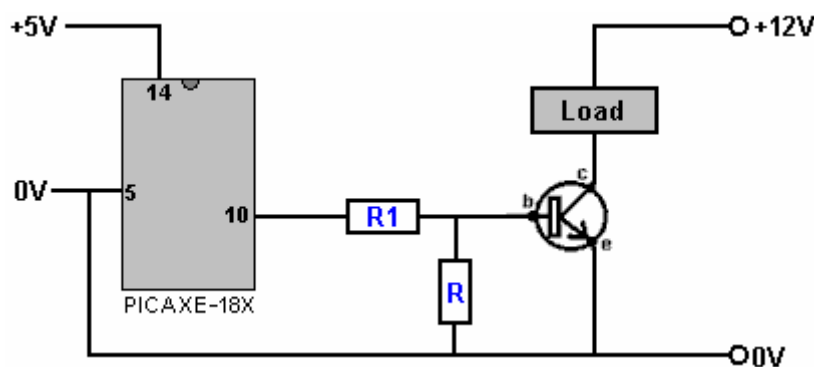

```
Main:
  high 4
  low 7
  pause 4
  low 4
  high 7
  pause 16
goto Main
```

These output voltages are then used in exactly the same way as the output voltages on pin 3 of a 555 chip, or any of the outputs of NAND gates, Hall-effect sensor chips, Schmitt triggers, or whatever. If the device to be powered requires very little current, then the easiest method is to connect the load directly to the output pin.

If, as is most often the case, the device to be powered needs a large current to make it work, then the output voltage is used to power a transistor, perhaps like this:

Here, the resistor "R1" limits the current fed into the base of the transistor when pin 10 goes high, but allowing enough current for the transistor to switch on fully, powering the load. The resistor "R" makes sure that the transistor switches off fully when the output on pin 10 goes low. The circuit as shown restricts the load to some piece of equipment which can operate on just five volts, so an alternative circuit could be:

This allows whatever voltage the load needs to be applied to the load, while the PIC chip remains running on its normal 5-volt supply. However, the equipment to be powered may not be able to have a common zero voltage connection with the PIC. To deal with this, an optical isolation chip can be used like this:

Here a high output voltage on pin 10 of the PIC chip lights up the LED inside the opto-isolator chip, causing a major drop in the resistance between the other two pins. This causes a current controlled by the resistor "R" to be fed into the base of the transistor, switching it on and powering the load.

Recently, a very popular programmable chip has been introduced. It is called the "Arduino" and it is fast and versatile and very popular with experimenters. There is an extensive set of English-language Video tutorials on the Arduino chip, the first in the series by Jeremy Blum is http://www.youtube.com/watch?v=fCxA9_kg6s. The board looks like this:

Capacitors.

We have avoided mentioning capacitors in any detail as it has not been necessary for understanding the circuitry covered so far. Capacitors come in many sizes, types and makes. Their size is stated in 'Farads' but as the Farad is a very large unit, you are unlikely to encounter a capacitor marked in anything larger than a microfarad, which is a millionth of a Farad. The symbol for a microfarad is μF where 'mu' is the letter of the Greek alphabet. This is a pain for normal text production as Greek letters do not occur in your average font. Some circuit diagrams give up on 'mu' and just write it as uF which looks like μF slightly mis-printed where the descender of the mu has not printed.

Anyway, very large capacitors which you may encounter range from 5,000 microfarads to maybe as much as 20,000 microfarads. Large capacitors range from 10 microfarads to 5000 microfarads. Medium sized capacitors run from 0.1 microfarad to about 5 microfarads and small capacitors are those below 0.1 microfarad.

1000 nanofarads ('nF') = 1 microfarad.

1000 picofarads ('pF') = 1 nanofarad

So:

0.01 microfarad can be written as 10nF

0.1 microfarad can be written as 100nF

0.1nF can be written as 100pF

Capacitors larger than 1 microfarad tend to be 'polarised'. In other words, the capacitor has a '+' connector and a '-' connector, and it does matter which way round you connect it. The larger capacitors have a voltage rating and this should **not** be exceeded as the capacitor can be damaged and possibly even totally destroyed. Capacitors can be added together, but surprisingly, they add in the reverse way to resistors:

Example 3

If two capacitors are wired in series, as shown in Example 1 above, the overall capacity is reduced while the voltage rating increases. The reduction in capacitance is given by:

$$1/C_t = 1/C_1 + 1/C_2 + 1/C_3 + \dots$$

In Example 1, then, $1/\text{total capacitance} = 1/100 + 1/100$ or $1/C_t = 2/100$ or $1/C_t = 1/50$ so the overall capacitance reduces from 100 microfarads to 50 microfarads. The advantage in wiring the capacitors like this is that the voltage rating has now increased to 32V (16V across each of the capacitors).

In Example 2, the overall capacitance has reduced to a third of 100 microfarads but the voltage rating has tripled.

In Example 3, the capacitors are wired in parallel. The voltage rating is unchanged but the overall capacitance is now the sum of the three capacitors, namely 300 microfarads.

There is no need for the capacitors to have similar values, there are merely shown that way in the examples to make the arithmetic easier and not distract you from the ways in which the capacitors interact together.

Occasionally, a circuit needs a large capacitor which is not polarised. This can be provided by placing two polarised capacitors back-to-back like this:

Example 4

Alternative Symbols

When the capacitors are connected this way, it does not matter which end of the pair is connected to the positive side of the circuit and which to the negative side.

Large capacitors usually have their capacitance and voltage printed on the outside of the capacitor, but small capacitors are usually far too tiny for that to be an option. So, a code very much like that used for resistors is used for small capacitors. The code is a 2-digit code for capacitors up to 100 picofarads and for higher values it is a 3-digit code where the first two digits are the numerical value of the capacitor in picofarads and the third digit is the number of zeros following the two digits. One thousand picofarads (pF) is one nanofarad (nF) and one thousand nanofarads is one microfarad. These are some common values:

Value	Code	Value	Code
10 pF	10	2.2 nF	222
22 pF	22	4.7 nF	472
47 pF	47	10 nF	103
100 pF	101	22 nF	223
220 pF	221	47 nF	473
470 pF	471	100 nF	104
1 nF	102	220 nF	224

The time has come for a serious warning: High voltages are very, very dangerous. Do not become so familiar with them that you treat them casually. **High voltages can kill you.** Capacitors are capable of building up high voltages and some good makes can hold the charge for several days.

In particular, do **not** try to make adjustments to, or take parts from, the inside of a TV set. A black and white TV set uses 18,000 Volts on the magnetic coils used to create the moving picture on the tube. A capacitor inside the set may well have that voltage on it three days after the set was last used. Don't fool around inside a TV set, it could kill you quick, or if you are really unlucky, it could injure you for life. A colour TV set uses 27,000 Volts to operate the coils inside it and that will fry you in jig time if you touch it.

Also, please don't think that you are safe if you don't quite touch it; 27,000 volts can jump across a gap to your hand. If you try to discharge a TV capacitor using a metal screwdriver with a wooden handle, please ensure that your medical insurance is up to date before you do it. You can receive a hefty shock through the screwdriver handle.

Voltages up to 24 Volts should be quite safe. **However**, some circuits will generate very high voltages even though the battery driving the circuit is low voltage. A standard off-the-shelf inverter circuit produces 240 Volts AC from a 12 Volt battery. Just because the battery is only 12 Volts does **not** mean that the circuit is not dangerous. Circuits which have inductors in them can produce high voltages, especially if they contain large capacitors. The voltage which produces the spark in your car engine is very high and it comes from the 12-volt car battery. You know enough about this by now, so **pay attention!**

The more advanced stuff:

You do not need to bother with this section if you are just starting out with some basic switching circuits of the type already described in this tutorial, so please feel free to skip this section and move on to the "Prototype Construction" section which you will find immediately useful.

This section is a lightweight introduction to Alternating Current circuits and pulsed DC circuits. Let me stress again that I am mainly self-taught and so this is just a general introduction based on my present understanding.

AC Power Factors.

Alternating Current, generally called "AC" is called that because the voltage of this type of power supply is not a constant value. A car battery, for instance, is DC and has a fairly constant voltage usually about 12.8 volts when in it's fully charged state. If you connect a voltmeter across a car battery and watch it, the voltage reading will not change. Minute after minute it says exactly the same because it is a DC source.

If you connect an AC voltmeter across an AC power supply, it too will give a steady reading, but it is telling a lie. The voltage is changing all the time in spite of that steady meter reading. What the meter is doing is **assuming** that the AC waveform is a sine wave like this:

and based on that assumption, it displays a voltage reading which is called the "Root Mean Square" or "RMS" value. The main difficulty with a sine wave is that the voltage is below zero volts for exactly the same length of time as it is above zero volts, so if you average it, the result is zero volts, which is not a satisfactory result because you can get a shock from it and so it can't be zero volts, no matter what the arithmetical average is.

To get over this problem, the voltage is measured thousands of times per second and the results squared (that is, the value is multiplied by itself) and then those values are averaged. This has the advantage that when the voltage is say, minus 10 volts and you square it, the answer is plus 100 volts. In fact, all of the answers will be positive, which means that you can add them together, average them and get a sensible result. However, you end up with a value which is far too high because you squared every measurement, and so you need to take the square root of that average (or "mean") value, and that is where the fancy sounding "Root Mean Square" name comes from – you are taking the (square) root of the (average or) mean value of the squared measurements.

With a sine wave like this, the voltage peaks are 41.4% higher than the RMS value which everyone talks about. This means that if you feed 100 volts AC through a rectifier bridge of four diodes and feed it into a capacitor the

capacitor voltage will **not** be 100 volts DC but instead it will be 141.4 volts DC and you need to remember that when choosing the voltage rating of the capacitor. In that instance I would suggest a capacitor which is made to operate with voltages up to 200 volts.

You probably already knew all of that, but it may not have occurred to you that if you use a standard AC voltmeter on a waveform which is **not** a sine wave, that the reading on the meter is most unlikely to be correct or anywhere near correct. So, please don't merrily connect an AC voltmeter across a circuit which is producing sharp voltage spikes like, for instance, one of John Bedini's battery pulsing circuits, and think that the meter reading means anything (other than meaning that you don't understand what you are doing).

You will, hopefully, have learned that power in watts is determined by multiplying the current in amps by the voltage in volts. For example, 10 amps of current flowing out of a 12 volt power supply, represents 120 watts of power. Unfortunately, that only holds true for circuits which are operating on DC, or AC circuits which have only resistors in them. The situation changes for AC circuits which have non-resistive components in them.

The circuits of this type which you are likely to come across are circuits which have coils in them, and you need to think about what you are doing when you deal with these types of circuit. For example, consider this circuit:

This is the output section of a prototype which you have just built. The input to the prototype is DC and measures at 12 volts, 2 amps (which is 24 watts). Your AC voltmeter on the output reads 15 volts and your AC ammeter reads 2.5 amps and you are delighted because $15 \times 2.5 = 37.5$ which looks much bigger than the 24 watts of input power. **But**, just before you go rushing off to announce on YouTube that you have made a prototype with $COP = 1.56$ or 156% efficient, you need to consider the real facts.

This is an AC circuit and unless your prototype is producing a perfect sine wave, then the AC voltmeter reading will be meaningless. It is just possible that your AC ammeter is one of the few types that can accurately measure the current no matter what sort of waveform is fed to it, but it is distinctly possible that it will be a digital meter which assesses current by measuring the AC voltage across a resistor in series with the output, and if that is the case, it will probably be assuming a sine wave. The odds are that both readings are wrong, but let's take the case where we have great meters which are reading the values perfectly correctly. Then the output will be 37.5 watts, won't it? Well, actually, no it won't. The reason for this is that the circuit is feeding the transformer winding which is a coil and coils don't work like that.

The problem is that, unlike a resistor, when you apply a voltage across a coil the coil starts absorbing energy and feeding it into the magnetic field around the coil, so there is a delay before the current reaches its maximum value. With DC, this generally doesn't matter very much, but with AC where the voltage is changing continuously, it matters a great deal. The situation can be as shown in this graph of both voltage and current:

At first, this does not look like any great problem, but it has a very significant effect on the actual power in watts. To get the 37.5 watts output which we were talking about earlier, we multiplied the average voltage level by the average current level. But these two values do not occur at the same time and that has a major effect.

As this can be a little difficult to see, let's take the peak values rather than the averages as they are easier to see. Let's say that in our example graph that the voltage peak is 10 volts and the current peak is 3 amps. If this were

DC we would multiply them together and say that the power was 30 watts. But with AC, this does not work due to the timing difference:

When the voltage is peaking, the current is nowhere near its peak value of 3 amps:

As a result of this, instead of getting our expected peak power at the top of the voltage peak, the actual power in watts is very much lower – less than half of what we were expecting. Not so good, but it gets worse when you look at the situation more closely. Take a look at what the voltage is when the current crosses the zero line, that is, when the current is zero. The output power is zero when the current is zero but this occurs when the voltage is at a very high value:

The same goes for when the voltage is zero. When the voltage is zero, then the power is also zero, and you will notice that this occurs when the current is at a high value:

The power is **not** the average current multiplied by the average voltage if there is a coil involved in the circuit – it will be less than that by an amount known as the “power factor” and I’ll leave you to work out why it is called that.

So, how do you determine what the power is? It is done by sampling the voltage and current many times per second and averaging those combined results:

Both the voltage and the current are sampled at the times indicated by the vertical red lines and those figures are used to calculate the actual power level. In this example, only a few samplings are shown, but in practice, a very large number of samples will be taken. The piece of equipment which does this is known as a wattmeter as it measures watts of power. The sampling can be done by windings inside the instrument, resulting in an instrument which can be damaged by overloading without the needle being anywhere near full deflection, or it can be done by digital sampling and mathematical integration. Most digital sampling versions of these meters only operate at high frequencies, typically over 400,000 cycles per second. Both varieties of wattmeter can handle any waveform and not just sine waves.

The power company supplying your home measures the current and assumes that the full voltage is present all of the time that the current is being drawn. If you are powering a powerful electric motor from the mains, then this current lag will cost you money as the power company does not take it into account. It is possible to correct the situation by connecting one or more suitable capacitors across the motor to minimise the power loss.

With a coil (fancy name “inductor” symbol “L”), AC operation is very different to DC operation. The coil has a DC resistance which can be measured with the ohms range of a multimeter, but that resistance does not apply when AC is being used as the AC current flow is **not** determined by the DC resistance of the coil alone. Because of this, a second term has to be used for the current-controlling factor of the coil, and the term chosen is “impedance”. The wire in any coil has a resistance and that opposes current flow through the coil irrespective of whether the voltage applied to the coil is DC or AC. The capacitance between the neighbouring turns of wire in a coil, introduces a feature of the coil which “impedes” AC current flow through the coil and the amount of that impedance depends on the frequency of the AC voltage being applied to the coil.

The impedance of a coil depends on it’s size, shape, method of winding, number of turns and core material. If the core is made up of iron or steel, (usually thin layers of iron which are insulated from each other), then it can only handle low frequencies. You can forget about trying to pass 10,000 cycles per second (“Hz”) through the coil as the core just can’t change it’s magnetisation fast enough to cope with that frequency. A core of that type is ok for the very low 50 Hz or 60 Hz frequencies used for mains power, which are kept that low so that electric motors can use it directly.

For higher frequencies, ferrite can be used for a core and that is why some portable radios use ferrite-rod aerials, which are a bar of ferrite with a coil wound on it. For higher frequencies (or higher efficiencies) iron dust encapsulated in epoxy resin is used. An alternative is to not use any core material and that is referred to as an air-core coil. These are not limited in frequency by the core but they have a very much lower inductance for any given number of turns. The efficiency of the coil is called it’s “Q” (for “Quality”) and the higher the Q factor, the better. The resistance of the wire lowers the Q factor.

A coil has inductance, and resistance caused by the wire, and capacitance caused by the turns being near each other. However, having said that, the inductance is normally so much bigger than the other two components that we tend to ignore the other two. Something which may not be immediately obvious is that the impedance to AC current flow through the coil depends on how fast the voltage is changing. If the AC voltage applied to a coil completes one cycle every ten seconds, then the impedance will be much lower than if the voltage cycles a million times per second.

If you had to guess, you would think that the impedance would increase steadily as the AC frequency increased. In other words, a straight-line graph type of change. That is not the case. Due to a feature called resonance, there is one particular frequency at which the impedance of the coil increases massively. This is used in the tuning method for AM radio receivers. In the very early days when electronic components were hard to come by, variable coils were sometimes used for tuning. We still have variable coils today, generally for handling large currents rather than radio signals, and we call them “rheostats” and some look like this:

These have a coil of wire wound around a hollow former and a slider can be pushed along a bar, connecting the slider to different winds in the coil depending on it's position along the supporting bar. The coil connections are then to the slider and to one end of the coil. The position of the slider effectively changes the number of turns of wire in the part of the coil which is in the circuit. Changing the number of turns in the coil, changes the resonant frequency of that coil. AC current finds it very, very hard to get through a coil which has the same resonant frequency as the AC current frequency. Because of this, it can be used as a radio signal tuner:

If the coil's resonant frequency is changed to match that of a local radio station by sliding the contact along the coil, then that particular AC signal frequency from the radio transmitter finds it almost impossible to get through the coil and so it (and only it) diverts through the diode and headphones as it flows from the aerial wire to the earth wire and the radio station is heard in the headphones. If there are other radio signals coming down the aerial wire, then, because they are not at the resonant frequency of the coil, they flow freely through the coil and don't go through the headphones.

This system was soon changed when variable capacitors became available as they are cheaper and more compact. So, instead of using a variable coil for tuning the radio signal, a variable capacitor connected across the tuning coil did the same job:

Resonance.

While the circuit diagram above is marked "Tuning capacitor" that is actually quite misleading. Yes, you tune the radio receiver by adjusting the setting of the variable capacitor, **but**, what the capacitor is doing is altering the resonant frequency of the coil/capacitor combination and it is the resonant frequency of that combination which is doing exactly the same job as the variable coil did on it's own.

This draws attention to two very important facts concerning coil/capacitor combinations. When a capacitor is placed across a coil "in parallel" as shown in this radio receiver circuit, then the combination has a very high impedance (resistance to AC current flow) at the resonant frequency. But if the capacitor is placed "in series" with the coil, then there is nearly zero impedance at the resonant frequency of the combination:

This may seem like something which practical people would not bother with, after all, who really cares? However, it is a very practical point indeed. In Chapter 3, some of the very high-power devices produced by Don Smith are described. Typically, he uses an off-the-shelf neon-tube driver module as an easy way to provide a high-voltage, high-frequency AC current source, typically, 6,000 volts at 30,000 Hz. He then feeds that power into a Tesla Coil which is itself, a power amplifier. The arrangement is like this:

People who try to replicate Don's designs tend to say "I get great sparks at the spark gap until I connect the **L1** coil and then the sparks stop. This circuit can never work because the resistance of the coil is too low".

If the resonant frequency of the **L1** coil does not match the frequency being produced by the neon-tube driver circuit, then the low impedance of the **L1** coil will definitely pull the voltage of the neon-tube driver down to a very low value. But if the **L1** coil has the same resonant frequency as the driver circuit, then the **L1** coil (or the **L1** coil/capacitor combination shown on the right, will have a very high resistance to current flow through it and it will work well with the driver circuit. So, no sparks, means that the coil tuning is off. It is the same as tuning a radio receiver, get the tuning wrong and you don't hear the radio station.

Choosing components which are not specified.

Some people find it difficult to select a suitable component where the exact component is not specified or where an alternative has to be selected, so perhaps a few general pointers might be helpful. The reason why component values are omitted may well be because a very wide range of alternative values can be used and if one particular is specified, the newcomers to electronics feel that they **have** to use that one value or the circuit will not work, (which is almost never the case). For example, I have been asked if a capacitor rated at 25V could be used instead of the same value capacitor rated at 16V shown in the circuit, to which the answer is 'yes, most definitely'. The lower voltage rating is adequate and the component cheaper to buy, but if one of a higher voltage rating is available, then it can be used.

With **capacitors**, you need to consider the physical size and wire connections, the capacitance, the voltage rating, and the leakage. The cost and size of a capacitor is directly related to it's voltage rating, and once the voltage rating exceeds that normally used, the price shoots up rapidly as the sales volume reduces rapidly, which in turn, discourages further sales. This sometimes causes circuit builders to connect chains of cheaper capacitors together to make a smaller-capacity high-voltage capacitor. In the case of Tesla Coil builders, they then may connect several of these chains in parallel to boost the capacitance.

If the voltage rating is exceeded (usually by a very large amount), the capacitor will be damaged and become either a short-circuit, or more likely, an open circuit. Either way, it will never work as a capacitor again. In a household circuit, where the capacitor is being used as part of the power supply to the circuit, the voltage rating does not need to be much higher than the supply voltage, with say, 16V being used for a 12V circuit. You could use a capacitor rated at 25V, 40V, 63V, 100V or 400V and it would work perfectly well, but it will be much larger and have cost much more. But, if you have one sitting around and not being used, there is no reason why you should not use it rather than paying to buy another one.

If the capacitor is being used in a timing circuit where a high-value resistor is feeding current to it, then the leakage current of the capacitor becomes very important. Electrolytic capacitors are seldom suitable for such an application as they have a small, unpredictable leakage current which will vary with the age of the capacitor. For accurate timing with a capacitor, ceramic, polypropylene, mylar or tantalum should be used.

The voltage rating for an electrolytic capacitor is for DC, so if you use it for limiting current in an AC power supply, that is, where the current flows through the capacitor rather than the capacitor being placed across the supply and is acting to combat ripple, then great care is needed. The capacitor will heat up due to the power flowing through it, and it is possible for an electrolytic capacitor used in that way to rupture or 'explode' due to the electrolyte boiling. Instead, you need to use the very much more expensive oil-filled can capacitors (as shown near the end of chapter 10). That style of usage is unusual for home constructors.

With bi-polar **transistors**, you need to use commonsense. Suppose a 555 timer chip is required to power a transistor which controls a relay:

For the moment, we will ignore the fact that the 555 could drive the relay directly without the need for a transistor. let's say that the relay draws a current of 30 mA when connected to a 12V supply. Therefore, the transistor needs to be able to handle a current of 30 mA. Any small switching transistor such as the BC109 or 2N2222 can easily handle that current. The transistor also needs to be able to handle 12 volts. If in doubt, look up the characteristics of your choice of transistor at <http://www.alldatasheet.co.kr/> by entering the transistor name 'BC109' or whatever in the entry box at the top of the screen and clicking on the button to the right of it. Eventually, it will let you download a pdf document specifying the transistor, and that will show you the voltages which the transistor can handle. Both of the above transistors can handle far more than 12V.

The next question is, 'can the transistor switch fast enough to work in this circuit?' and the data sheet will show that they can switch on and off a million times per second. As the relay can only switch on and off a few times per second, the transistor can easily operate fast enough to handle the switching.

Next, we need to know what size of resistor would be suitable. The data sheet will also show the DC current gain of the transistor. This is usually marked as "hfe" and for these transistors is likely to be a minimum of, say, 200. This means that the current flowing into the base of the transistor needs to be one two-hundredth of the relay's 30 mA which is 0.15 mA. The resistor will have about +11 volts at pin 3 of the 555 timer and around +0.7 volts at the base of the transistor when it is switched fully on. That means that the resistor will have about 10.3 volts across it when the relay is switched on:

So, what size of resistor will have 0.15 mA flowing through it when there is a 10.3-volt drop across it? We know that a 1K resistor passes 1mA per volt and so would pass 10.3 mA with 10.3 volts across it. That is far more than we need. A 10K resistor would pass 1.03 mA which is still far too much but certainly could be used. As it is a resistor, we can use Ohm's Law: $R = V / A$ (Ohms equals Volts over Amps), or $R = 10.3 / 0.00015$ which is 68K. So, any resistor between 68K and perhaps 15K should work well.

The diode is there to protect the transistor from excessive voltage caused by the coil of the relay. When a coil is switched off suddenly, it generates a reverse voltage which can be hundreds of volts, pulling the collector of the transistor far above the +12V power supply line. When that starts to happen, it effectively reverses the diode direction, allowing it to conduct and short-circuit that big voltage spike:

Due to the short-circuiting, the voltage can't get any higher and the current through the diode is not large, so most diodes such as the popular and cheap 1N4001 or 1N4007 types can be used.

When a transistor is connected like that and switched on, it is effectively a short-circuit between its collector and emitter, and that places the full 12 volts across the relay, powering it very solidly. This connection method is called a "common-emitter" circuit because all of the transistors used have their emitters all wired in common to the 0V line. An alternative arrangement is the "emitter-follower" circuit:

With this circuit arrangement, the emitter of the transistor "follows" the voltage on pin 3 of the 555 timer. It is always a constant voltage below it, typically about 0.7 volts. The output of the 555 timer has a maximum of about 0.7V below the supply voltage, and so its maximum value is about 11.3V in this circuit. The transistor drops that by a further 0.7V, which means that the relay only gets about 10.6V across it instead of the full 12V of the supply, which means that it should be a 10-volt relay rather than a 12-volts relay.

Those are the easy cases because the 555 timer can supply at least 200 mA through its output pin, while keeping the output voltage steady. That is not the case with simple transistor circuits. Take a situation like this:

For audio work - microphone pre-amplifiers and the like – the rule of thumb is that the current flowing through the first transistor should be at least ten times the current required by the base of the second transistor in order not to drag down and distort the audio waveform.

Relay switching is not so critical but the same general principle applies and attention needs to be paid to the collector resistor of the preceding transistor. For example, if the current flowing through the preceding transistor is small, say, 0.5 mA and the output transistor needs 1.5 mA flowing into its base, then there can be a problem. In this circuit, for example:

Here, the voltage at point "A" goes high because the first transistor switches off and so becomes the same as a resistor of 1Meg or more. Normally, that resistance is so much greater than the 27K of its resistor, that the voltage at point "A" would be nearly +12V, but if you were to connect the resistor "R" of just 1K in value, then the situation is changed completely. The base of "Tr" can't rise above 0.7V. The first transistor can be ignored due to its very high resistance. That leaves a voltage-divider pair of resistors, the 27K and the 1K, with 11.3 volts across them, stopping the voltage at point "A" from rising above 1.13V instead of the original 12V and transistor "Tr" will only get 0.43 mA instead of the 1.5 mA which was wanted. The transistor "Tr" has effectively a 28K resistor feeding it current from the +12V rail.

One solution would be to raise the current through the first transistor by using a resistor a good deal smaller than the present 27K. Another option is to lower the input current requirement of transistor "Tr" by making it a Darlington pair or by using a transistor with a much higher gain.

Constructing Prototypes.

The main options for building a prototype circuit are:

1. A (plug-in) breadboard
2. Electrical screw connector strips.
3. Stripboard
4. A printed circuit board.

1. The typical breadboard unit consists of a matrix of clip holes wired in strips, into which component leads can be pushed to make a circuit. In my opinion, they are best avoided as it takes quite some effort to implement any significant circuit using them, some components do not fit well in the sockets which are small enough to take DIL IC packages, and when you do get a circuit working well on the breadboard, there is no guarantee that it will work well when you attempt to move it to a permanent soldered board:

While a plastic board of this type looks as if it should be quick and easy to use, I have never found it to be so ever since the boards were scaled down in size to take the closely-spaced pins of integrated circuits ("chips"). It is generally difficult to lay the components out in the same pattern as the circuit diagram, and if they are not, then it becomes slow to follow the circuit through on the breadboard layout.

2. The local hardware shop has cheap screw connectors which can be very effective. These come in several sizes and the smaller ones are very convenient for constructing transistor circuitry. They look like this:

Circuits can be assembled very easily, using these connectors and an example might be one of the John Bedini battery pulsing circuits which might have a layout like this:

I have built this circuit using this style of construction and it was very successful indeed, being very quick and easy to construct and it proved to be very tough and effective over a long period of use. The plastic strip has a hole between each connector strip and that allows you to bolt the strip to a base board on which you mount other components, in this case, the pulsing coil and the rotor with the magnets attached. Each connection block can take two or three wires. The wires need to have the insulation removed and the wires scraped clean and shiny if they are not already in that state. If more than one multi-strand wire is being put into one side of a connector, then it is usually best to twist the wires together before tightening the clamping screw. If you want, you can give the twisted wires a thin coat of solder, but this has to be done neatly to avoid producing a joint which is too large to fit into the connector. One connector can be cut out of the strip quite easily, using a pair of scissors or a craft knife. Single connectors can join two wires very effectively without the need to solder them.

3. Stripboard, usually called 'Veroboard' even if it is not made by Vero, is a quick and satisfactory method, although you have to make very tiny solder joints. Please be aware that the fumes from the burning resin when soldering are most definitely not good for your health and should be avoided by making sure that the ventilation is adequate.

4. A printed circuit board is feasible for a one-off prototype and making one will increase your production skills, so it is also a reasonable option if you have the etching and drilling equipment to hand. Buying all of the necessary equipment if you do not have any, can cost a fair amount, but the skills gained are significant and the finished boards looks very professional.

There are several other methods of construction, and many varieties of construction board and stripboard. Simple stripboard will be used in the following descriptions, although the method does apply to many different styles of construction.

The first step is to produce a layout for the components on the board. When designing the layout provision should be made for drilling holes to allow the completed board to be bolted to its case using bolts and insulating pillars to keep the soldered joints clear of all other surfaces.

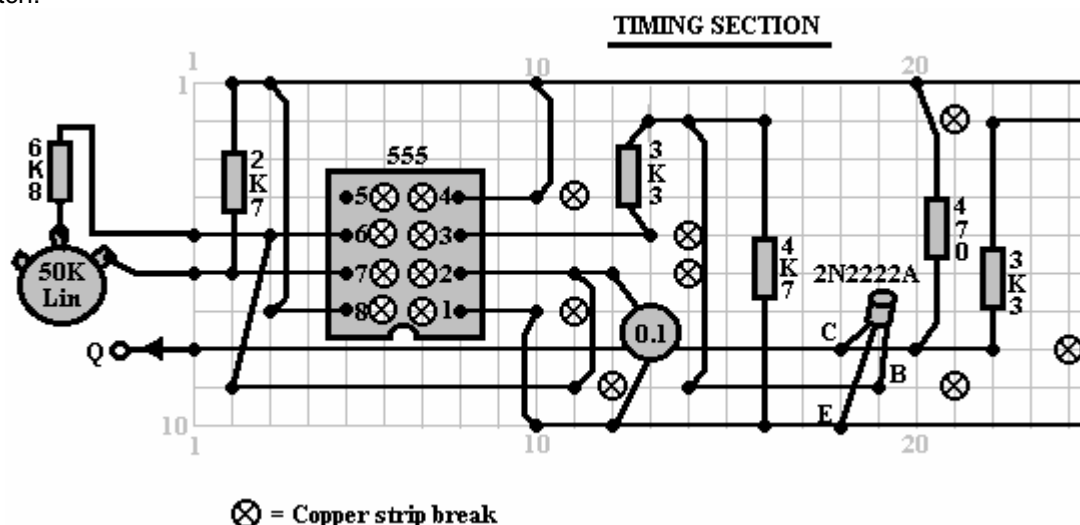

The circuit diagram of the circuit to be built is the starting point. You might wish to draw a light grid of lines to represent the matrix of holes in the strip board. This helps to visualise the run of the copper strips and the sketch can be made to show the exact number of holes available on the piece of strip board to be used. The strip board looks like this:

So you might wish to produce a layout sketch re-usable drawing like this:

where the horizontal strips are numbered and the vertical lines of holes are also numbered. In this sketch, where the lines cross, represents a hole in the board. The sketch of a possible physical layout can then be prepared and it might look like this when seen from the top although the copper strips on the underside of the board are shown in the sketch:

It is very important when producing a sketch like this, that the copper strips making up the circuit are not accidentally used to connect components further along the board, without breaking the copper strip between the

two sections of the board. It helps to mark a copy of the circuit diagram when you are sketching a possible physical layout on the strip board. It might be done like this:

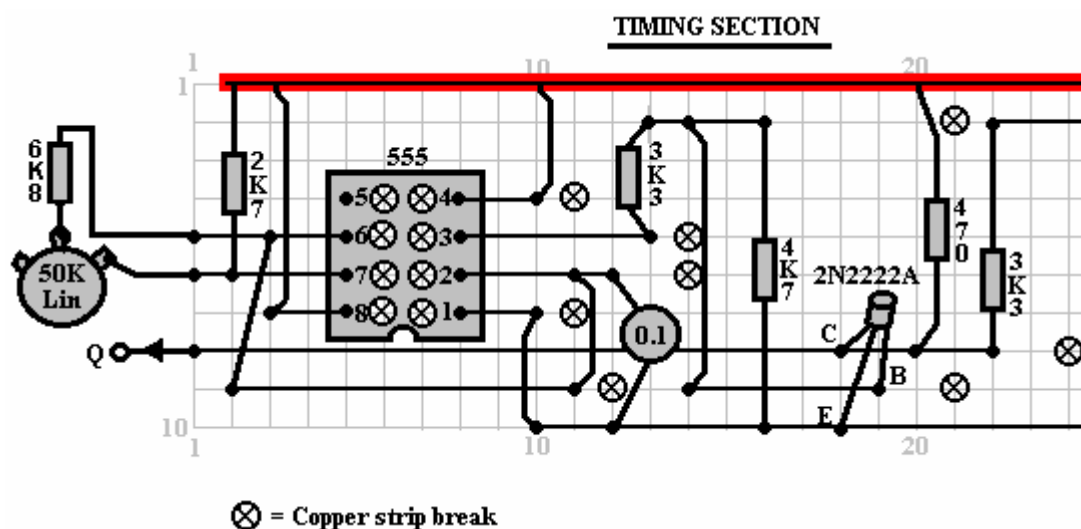

Here, the components just below the diode are ringed to show that they have been marked on the layout sketch and, if necessary, the copper strip broken to isolate the components. A component worth mentioning in passing, is the capacitor marked with red in the circuit diagram. This is a decoupling capacitor, fed from the 12V battery via a resistor and a diode (a diode is not normally used in this part of the circuit).

The decoupling is to provide the 555 chip and drivers with a supply which is reasonably isolated from the heavy current-draw circuit not shown in this small section of the circuit diagram. The pulsating heavy current draw of the rest of the circuit is capable of pulling the battery voltage down slightly many times per second. This creates a voltage ripple on the positive supply line from the battery and to smother the ripple, the resistor and diode are used to feed a large reservoir capacitor which smoothes out the ripple.

The circuit itself is not beyond criticism. Transistor 'TR2' and its associated components are redundant since pin 3 of the 555 chip already supplies the required signal (and with higher drive capacity) so the second output line should be taken directly from pin 3 of the 555 chip. This snippet of circuit is only shown here as an example of marking up a circuit diagram when making a components layout sketch.

As the layout sketch is produced, the circuit diagram should be marked off with a highlighting pen to make sure that every part of the circuit diagram has been successfully copied to the sketch. In the example below, not all of the highlighted strip is shown, since it runs off the small section of the board being shown here:

Many electronic components can be damaged by the high temperatures they are subjected to when being soldered in place. I personally prefer to use a pair of long-nosed pliers to grip the component leads on the upper side of the board while making the solder joint on the underside of the board. The heat running up the component lead then gets diverted into the large volume of metal in the pair of pliers and the component is protected from excessive heat. On the same principle, I always use a DIL socket when soldering a circuit board, that way, the

heat has dissipated fully before the IC is plugged into the socket. It also has the advantage that the IC can be replaced without any difficulty should it become damaged.

If you are using CMOS integrated circuits in any construction, you need to avoid static electricity. Very high levels of voltage build up on your clothes through brushing against objects. This voltage is in the thousands of volts range. It can supply so little current that it does not bother you and you probably do not notice it. CMOS devices operate on such low amounts of current that they can very easily be damaged by your static electricity. Computer hardware professionals wear an earthing lead strapped to their wrists when handling CMOS circuitry. There is no need for you to go that far. CMOS devices are supplied with their leads embedded in a conducting material. Leave them in the material until you are ready to plug them into the circuit and then only hold the plastic body of the case and do not touch any of the pins. Once in place in the circuit, the circuit components will prevent the build up of static charges on the chip.

Soldering is an easily-acquired skill. Multi-cored solder is used for electronic circuit soldering. This solder wire has flux resin contained within it and when melted on a metal surface, the flux removes the oxide layer on the metal, allowing a proper electrical joint to be made. Consequently, it is important that the solder is placed on the joint area and the soldering iron placed on it when it is already in position. If this is done, the flux can clean the joint area and the joint will be good. If the solder is placed on the soldering iron and then the iron moved to the joint, the flux will have burnt away before the joint area is reached and the resulting joint will not be good.

A good solder joint will have a smooth shiny surface and pulling any wire going into the joint will have no effect as the wire is now solidly incorporated into the joint. Making a good solder joint takes about half a second and certainly not more than one second. You want to remove the soldering iron from the joint before an excessive amount of heat is run into the joint. It is recommended that a good mechanical joint be made before soldering when connecting a wire to some form of terminal (this is often not possible).

The technique which I use is to stand the solder up on the workbench and bend the end so that it is sloping downwards towards me. The lead of the component to be soldered is placed in the hole in the strip board and gripped just above the board with long-nosed pliers. The board is turned upside down and the left thumb used to clamp the board against the pliers. The board and pliers are then moved underneath the solder and positioned so that the solder lies on the copper strip, touching the component lead. The right hand is now used to place the soldering iron briefly on the solder. This melts the solder on the joint, allowing the flux to clean the area and producing a good joint. After the joint is made, the board is still held with the pliers until the joint has cooled down.

Test Equipment.

When developing new circuitry, it may be convenient to try different values of resistor in some position in the circuit (the resistor value may be dependent on the gain of a transistor or the actual resistance of an ORP12, or some such other situation). For this, it is very convenient to have a resistor-substitution box which allows you to select any standard resistor at the turn of a switch.

These are not readily available on the market. In years gone by, it was possible to buy custom wafer switches, where the number of wafers could be built up to whatever switch size was required, but these do not seem to be available any more. A slightly less convenient method of construction is to use four of these, selected by a second wafer switch:

In the above diagram, all of the resistors in one range (100 ohms to 820 ohms, 1K to 8K2, 10K to 82K or 100K to 820K) are wired to a single 12-way switch. The output wires then have any of these standard resistors across

them, depending on the setting of the switch. A second switch can then be used to select several of these groups, while still using the same output wires. When boxed, it might look like this:

It can also be useful to have a versatile signal generator. You can easily construct your own with variable frequency, variable mark/space ratio and optional variable gating. If you do, you might as well make it with a low output impedance so that it can drive devices under test directly rather than having to provide additional buffering. It might look like this:

The really essential item of equipment is a multimeter. These come in many shapes, sizes and varieties and the cost varies enormously. The reliability also varies a great deal. The most reliable and the cheapest is the analogue type which does not use a battery (other than for the occasional measurement of resistance). Although these types are looked down upon nowadays, they are 100% reliable:

The meter shown above is rated at 2,000 ohms per volt, so connecting it to a circuit to make a measurement on the 10V range is the same as connecting a 20K resistor to the circuit. The big brother of this style of equipment is about five times larger and has 30,000 ohms per volt performance, so connecting it on a 10V range is the same as connecting a 300K resistor to the circuit being measured. This one is battery driven, so if you get one of these, may I suggest that you check its accuracy on a regular basis:

The really excellent non-battery (ex-professional) Avo meter multimeters are still available through eBay at affordable prices. These have 30,000 ohms per volt performance and are robust and accurate, having been built to very high standards.

A multimeter uses a 1.5V battery to measure resistance. Ohm's Law is used as the working principle and the operation is:

The meter shown in the diagram has a small resistance of its own. This has a small variable resistor added to it. This variable resistor will have a small knob mounted on the face of the multimeter, or it will be a thumbwheel knob projecting slightly from the right hand side of the multimeter case. The 1.5V battery will be positioned inside the multimeter case as is the 1K resistor. To use the resistance ranges, the multimeter probes are touched firmly together to form a short-circuit and the variable resistor adjusted so that the meter points to zero.

For the purpose of this discussion, let us assume that the internal resistance of the meter, when correctly adjusted, is exactly 1K. If the resistor under test is exactly 1K in value, then the current through the meter will be halved and the meter will show a needle deflection half way across the scale. If the resistor under test is 2K, then the current will be one third and the scale marking will be at the 1/3 position from the left. If the resistor is 4K, then there will be one fifth ($1K+4K=5K$) of the full-scale current and the 4K mark will be 20% from the left hand side of the scale.

Two things to notice: firstly, the scale has to read from right to left which can take some getting used to, and secondly, the scale is not linear, with the markings getting closer and closer together and consequently, more difficult to mark and read, the higher the value of the resistor being measured. The bunching up of the scale markings is why the more expensive multimeters tend to have more than one range.

A mains-operated oscilloscope is an excellent piece of equipment to own but they are expensive when new. It is possible to pick one up at a reasonable price second-hand via eBay. An oscilloscope is by no means an essential item of equipment. One of its most useful features is the ability to measure the frequency, and display the shape of a waveform. Most waveforms are of known shape so the frequency is the major unknown. The following meter is not expensive and it displays the frequency of a signal on a digital readout:

So, when you are deciding what multimeter to buy, consider the following points:

1. How reliable is it? If you are opting for a battery driven unit, what happens to the accuracy if the battery starts to run down. Does it display a warning that the battery needs to be replaced? Mains-operated digital multimeters are brilliant but are a problem if you want to make measurements away from the mains.
2. What DC voltage ranges does it have? If you are intending to work mainly with 12V circuits, it is inconvenient for the ranges to be 9V and 30V as successive ranges. Digital meters do not have this problem but the question then is, how accurate are they going to be in day to day use?
3. Transistor testing options you can ignore - you are better off making your own dedicated unit to check transistors if you think you will ever need to do this - you probably won't.
4. Measuring current can be very useful so see what ranges are offered.
5. Measuring capacitance is very useful, especially since many capacitors are not well marked to indicate their value.
6. Measuring the frequency of a waveform could be a significant bonus but the question is; are you every likely to need it?
7. Measuring resistance is very useful. Every meter has it. There is no need to be over fancy on measurement ranges as you usually only need to know the approximate answer - is it a 1K resistor or a 10K resistor?

Look around and see what is available, how much it costs and what appeals to you. It might not be a bad idea to buy a really cheap multimeter and use it for a while to see if it has any shortcomings which are a nuisance, and if so, what improvements you personally want from a more expensive meter.

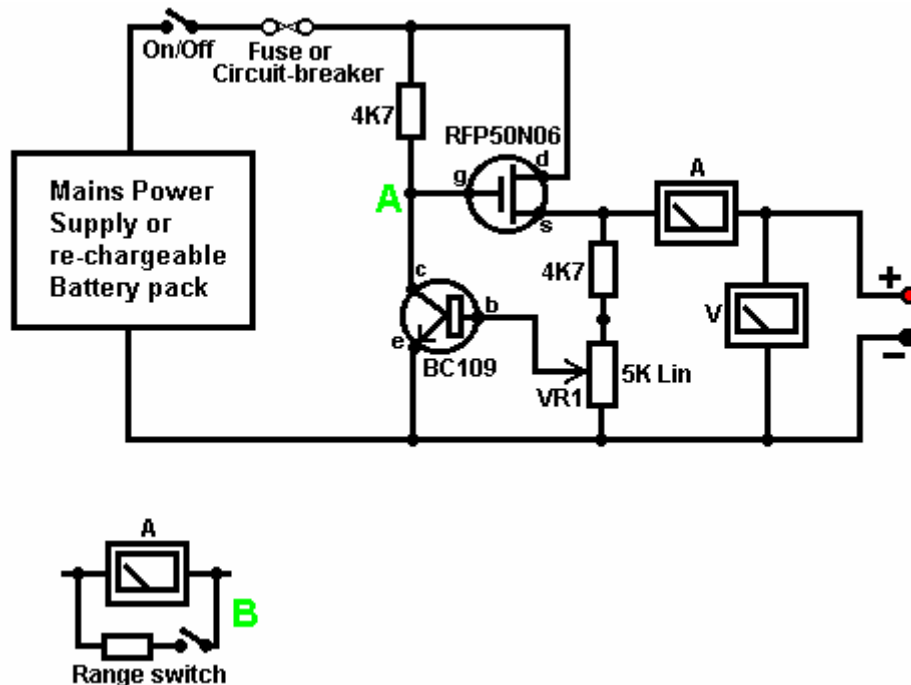

The 'Bench' Power Supply.

It might be worth getting a fancy bench power supply which allows you to set any voltage you want and which displays the current being drawn by your development circuit:

However, there is no need to spend money on a fancy unit when you can build an excellent unit of your own with voltage stabilisation, adjustable output, metered current, etc. etc. Personally, if developing a circuit to be used with a battery, I believe you are better off powering the development from a battery, that way the characteristics of the battery are included in any tests which you carry out.

If you wish, you can construct a very convenient development test bed power supply system. This has the advantage that you can make it in the most convenient style for your own use. You can also make the protection ultra-sensitive and build in additional circuitry such as transistor tester and resistor substitution box to produce an integrated test bed. You could perhaps use a circuit like this:

Here, the power is supplied by a pack of re-chargeable Ni-Cad batteries or possibly, a mains unit with voltage stabilisation. As in all actual circuits, the next thing in the circuit is **always** an on/off switch so that the power source can be disconnected immediately should any problem arise. Next, as always, comes a fuse or circuit breaker, so that should the problem be serious, it can disconnect the circuit faster than you can react. If you wish, you can build your own super-accurate adjustable circuit breaker to use in this position.

The two transistors and three resistors form an adjustable, stabilised output. The FET transistor has a high output power handling capacity and a very low input power requirement and so is good for controlling the output voltage.

Resistor 'VR1' is padded with the 4K7 resistor solely to reduce the voltage across the variable resistor. VR1 is adjusted to control the output voltage. If the current draw is increased and the output voltage is pulled down slightly, then the voltage on the base of the BC109 transistor is reduced. This starts to turn the transistor off, raising the voltage at point 'A', which in turn, raises the output voltage, opposing the variation caused by the load.

The output is monitored, firstly by a large milliammeter to show the current draw and secondly, on the output side of the milliammeter, a voltmeter. This allows very close monitoring of the power supplied to the prototype, especially if the milliammeter is placed alongside the prototype. You can build this circuit into a wide flat box which provides a working surface beside the milliammeter.

At point 'B' in the above diagram, a method for altering the current range of the milliammeter by placing a 'shunt' resistor across it. When the switch is closed, some current flows through the resistor and some through the milliammeter. This resistor has a very low value, so you are better off making it yourself. Let's say we wish to double the range of the meter. Solder the switch across the meter and for the resistor use a length of enamelled copper wire wound around a small former. Put a load on the output so that the meter shows a full-scale deflection. Close the switch. If the current displayed is exactly half of what it was, if not, switch off, remove some wire to lower the reading or add some wire to raise the reading and repeat the test until exactly half the current is displayed. The lower the value of the shunt resistor, the more current flows through it and the less through the meter, which then gives a lower reading.

Please note: it is very important to have a fuse or circuit breaker in the power being delivered to your test circuit. Any error in building the prototype can cause a major current to be drawn from the supply and **this can be dangerous**. Remember, you can't see the current. Even if you have a meter on the current being delivered, you may not notice the high reading. The first sign of trouble may be smoke! You can easily fry the circuit you are building if you do not have a safety cut-off, so use a fuse or other device which limits the current to twice what you are expecting the circuit to draw.

So, after all that, what equipment do you really need? You need a small soldering iron and multicore solder, a pair of long-nosed pliers and a multimeter. One other thing is some tool to cut wires and remove the insulation prior to soldering. Personal preferences vary. Some people prefer one of the many custom tools, some people use a knife, I personally use a pair of straight nail scissors. You pick whatever you are comfortable with.

Not exactly a vast array of essential equipment. The other items mentioned are not by any means essential so I suggest that you start by keeping things simple and use a minimum of gear.

If you are not familiar with electronics, I suggest that you get a copy of the Maplin catalogue, either from one of their shops or via the <http://www.maplin.co.uk> web site. Go through it carefully as it will show you what components are available, how much they cost and often, how they are used. The specifications of almost any semiconductor can be found free at <http://www.alldatasheet.co.kr> in the form of an Adobe Acrobat document.

Finally, because it is not important, all of the circuitry shown so far has indicated current flowing from the + of a battery to the - terminal. The discovery of voltage was made by Volta but he had no way of knowing which way the current was flowing, so he guessed. He had a 50 - 50 chance of getting it right but he was not lucky and got it wrong. Electrical current is actually a flow of electrons, and these flow from the battery minus to the battery plus. So, who cares? Almost nobody, as it has no practical effect on any of the circuitry. Some useful websites:

<http://www.esr.co.uk> for components
<http://www.maplin.co.uk> for components
<http://www.alldatasheet.co.kr> for semiconductor specifications
<http://www.cricklewoodelectronics.com> for components
<http://www.greenweld.co.uk> for components

The Oscilloscope.

If you do decide that you are going to research new equipment, design and possibly invent new devices, then an oscilloscope is useful. Let me stress again that this is not an essential item of equipment and most certainly is not needed until you are quite familiar with constructing prototypes. It is quite easy to misread the settings of an oscilloscope and the methods of operation take some getting used to. The low-cost book "How to Use Oscilloscopes and Other Test Equipment" by R.A. Penfold, ISBN 0 85934 212 3 might well be helpful when starting to use a 'scope.

It is possible to get an oscilloscope at reasonable cost by buying second-hand through eBay. The best scopes are 'dual trace' which means that they can display the input waveform and the output waveform on screen at the same time. This is a very useful feature, but because it is, the scope which have that facility sell at higher prices.

The higher the frequency which the scope can handle, the more useful it is, but again, the higher the selling price. Not all scopes are supplied with (the essential) 'test probes', so it might be necessary to buy them separately if the seller wants to keep his. Getting the manual for the scope is also a decided plus. A low cost scope might look like this:

Measuring Magnetic Field Strength.

People who experiment with permanent magnets, can make use of an instrument which displays the strength of a magnetic field. Professionally made devices to do this tend to be well outside the purchasing power of the average experimenter who will already have spent money on materials for his prototypes. Here is a design for a simple and cheap circuit, powered by four AA dry cell batteries, and utilising a Hall-effect semiconductor as the sensor:

This design uses an OP77GP operational amplifier chip to boost the output signal from the A1302 chip which is a Hall-effect device. The gain of the DC-connected operational amplifier is set by the ratio of the 1K and 1M fixed resistors shown shaded in the circuit diagram, giving a gain of 1,000.

The circuit operation is simple. The six-volt battery charges the 10 microfarad capacitor which helps iron out any supply line fluctuations caused by varying current draw by the circuit. The 10K variable resistor is used to set the

output meter display to zero when the Hall-effect device is not near any magnet. The 1K variable resistor is there to make fine tuning adjustments easier.

When the A1302 chip encounters a magnetic field, the voltage on it's output pin 3 changes. This change is magnified a thousand times by the OP77GP amplifier. It's output on pin 6 is connected to one side of the display meter and the other side of the meter is connected to point "A". The voltage on point "A" is about half the battery voltage. It would be exactly half the voltage if the two 4.7K resistors were exactly the same value. This is rather unlikely as there is a manufacturing tolerance, typically around 10% of the nominal value of the resistor. The exact value of the voltage on point "A" is matched by the OP77GP tuning and so the meter reads zero until a magnetic field is encountered. When that happens, the meter deflection is directly proportional to the strength of the magnetic field.

The Weird Stuff.

You don't need to know the following information, so please feel free to skip it and move on to something else.

The presentation shown above is based on the conventional view of electronics and electrical power as taught in schools and colleges. This information and concepts works well for designing and building circuits, but that does not mean that it is wholly correct. Unfortunately, the world is not as simple as is generally made out.

For example, it is said that current is a flow of electrons passing through the wires of a circuit at the speed of light. While it is true that some electrons do actually flow through the metal of the wires, the small percentage of electrons which actually do that, do it quite slowly as they have to negotiate their way through the lattice of the molecules of metal making up the body of the wires.

In spite of this, when the On/Off switch of a circuit is flipped on, the circuit powers up immediately, no matter how long the wires are. The reason for this is that electrical current flows along the wires at very high speed indeed, but it flows rapidly **along** the outside of the wires, not rapidly **through** the wires. One thousandth of a second after switching on a circuit, the electrons flowing through the wires have hardly got started, while the current flowing along the outside of the wires has gone all around the circuit and back:

The above sketch does not show the proportions correctly, as the current flow spiralling along the outside of the wire should be hundreds of thousands of times longer than shown, which is not practical in a diagram.

The actual path taken by current flow makes the surface of the wire of particular importance, and the insulation material is also of great importance. In years gone by, wire manufacturers used to anneal (cool down) copper wires in air. This created a layer of cupric oxide on the outer surface of copper wires, and that layer gave the wire different characteristics than copper wire has today. William Barbat in his patent application claims that the cupric oxide layer can be utilised in making devices with greater power output than the power input from the user.

Unfortunately, the world is not quite as simple as that, as power flowing in a circuit has at least two components. The electrical current which we measure with ammeters is as described above and is sometimes referred to as "hot" electricity as when it flows through components, it tends to heat them up. But there is another component referred to as "cold" electricity, so named because it tends to cool components down when it flows through them. For example, if the output wires of Floyd Sweet's VTA device were short circuited together, frost would form on the device due to the heavy flow of "cold" electricity, and getting a "shock" from it could give you frostbite instead of a burn.

"Cold" electricity is not something new, it has always been there as it is just one aspect of "electricity". It has not been investigated much by conventional science because none of the instruments used to measure "hot" electricity, react to "cold" electricity at all. (Actually, "hot" electricity, "cold" electricity and magnetism are all features of a single entity which should really be called "electromagnetism").

Now the spooky bit: "cold" electricity does not flow along or through the wire at all. Instead, it flows in the space around the wire, possibly riding on the magnetic field caused by the "hot" current. Thomas Henry Moray is famous for building a device which captured "cold" electricity and produced a massive power output capable of powering a whole host of ordinary electrical pieces of equipment. In his many public demonstrations before he was intimidated into silence and his equipment smashed, he invited members of the audience to bring a piece of ordinary glass with them. Then, when his circuit was powering a row of lights, he would cut one of the wires and

insert the piece of glass between the cut ends of the wires. This had no noticeable effect on his circuit, with the power flowing happily through the glass and on through his circuit, powering the lights just as before. That does not happen with "hot" electricity, but as the "cold" electricity is not flowing through or along the surface of the wire, a break in the wire is not a major obstacle to it.

We still do not know very much about "cold" electricity. Edwin Gray snr. demonstrated light bulbs powered by "cold" electricity being submerged in water. Not only did the bulbs continue to operate unaffected by the water, but Edwin often put his hand in the water along with the lit bulb, suffering no ill effects from doing so. Neither of those two effects are possible with conventional electricity, so please **don't** try them to check it out.

Another interesting item is the water-powered car system produced by an American man Nathren Armour. His system, (among other things) involves feeding extra electrical power to the spark plugs. One thing which has always puzzled him is that the engine will not run with just one wire going to the spark plug cap. He has to have a second wire running from his extra power supply to the body of the plug where it screws into the engine block. Take that wire away and the engine stops. Put it back again and the engine runs. But according to conventional electrics, that wire cannot possibly be needed, because the engine block is grounded and the power supply output is grounded, so in theory, there is no voltage difference between the ends of the wire, therefore no current can flow along the wire, hence the wire is not needed and has no function. Well, that is true for "hot" electricity, but it seems possible that the Nathren Armour system is using "cold" electricity as well as "hot" electricity and the "cold" electricity needs the extra wire as a flow guide to the spark plug.

Enough about that for now. Let's go one step further into the "weirdness" of the actual world. If, three hundred years ago, you had described X-rays, gamma rays, nuclear energy and TV signals to the average well-educated person, you would have run a considerable risk of being locked up as being mad. If you do it today, your listener would probably just be bored as he already knows all this and accepts it as a matter of fact (which it is). Please bear that in mind when you read the following information. If it seems strange and far-fetched, that is only because conventional science today is lagging badly behind and still teaching things which have been conclusively proven to be wrong decades ago.

If you lived in a desert and every day a company drove in with a lorry-load of sand and sold it to you for a large amount of money, what would you think about that? Not a very good deal for you, is it? What's that you say, you would never do that? But you already do, because you don't realise that the sand is all around you ready for the taking at next to no cost at all. Several people have tried to publicise the fact, but the sand company has immediately silenced them by one means or another. The company does not want to lose the business of selling you the sand and definitely doesn't want you to start picking it up for yourself for free.

Well... to be perfectly fair, it is not actually sand, it is energy, and it is all around us, free for the taking. Sound a bit like X-rays did three hundred years ago? Doesn't mean that it is not true. It is perfectly true. The design of all computers made today is based on the equations of Quantum Mechanics, and while those equations are not yet perfect, they are easily good enough for practical purposes. The snag is that the world seen at the level of the quantum is not much like the world we think that we see around us and which we think that we understand fully. Examining the world at the quantum level shows that we live in a seething mass of incredible energy. Einstein is famous for stating that Mass equals a very large amount of Energy, a fact that is shown clearly when an atomic bomb is detonated. Put in different words, a small amount of matter is the equivalent of a very large amount of energy. Actually, Energy and Matter are two different aspects of a single thing (which could reasonably be called "Mass-Energy").

At the quantum level, it can be seen that particles of matter pop into existence and drop out again into energy on a continuous basis, everywhere in the whole of the universe. The whole universe is seething with energy. That energy doesn't bother us any more than water bothers a fish, as we evolved in this sea of energy and we just don't notice it. It doesn't harm us, but if we wanted, and knew how, we could use as much of that energy as we wanted for ever and ever. The amount of that energy is unbelievable. It has been calculated that one cubic centimetre anywhere in the universe contains enough energy to create all of the matter we can see in the whole of the universe. Think how many cubic centimetres there are in the Earth ... the Solar System ... our Galaxy ... If every person on Earth were to run their vehicles, power their homes, fly their planes, etc. etc. for the next million years, it would not make the slightest dent in the energy contained in one cubic millimetre of the universe. This is not a theory, it is a fact. (Would you like to buy a big pile of sand? - I've got a load just over here...). This big energy field has gone under different names over the years. A popular name at the present time is the "Zero-Point Energy Field" and it is responsible for everything that happens in the universe. It powers life itself. It balances out in equilibrium everywhere, which is one reason which makes it hard to realise that it is all around us.

Tom Beardon is an American man with very considerable abilities and considerable in-depth knowledge of how the world actually operates. His statements are generally based on laboratory-proven criteria backed up by his high level of mathematical skills which give him an additional grasp of things. He explains how electricity actually works in circuits, and it is nothing like the system taught in schools and colleges. We think that when we attach a

battery to an electrical circuit, the battery forces a current through the wires of the circuit. Sorry Chief - it is actually nothing like that at all. The power in the circuit comes directly from the Zero-Point Energy Field and has very little to do with the battery at all. We tend to think of "using up" power, but that is just not possible. Energy cannot be destroyed or "used up" the most you can do to it is to change it from one form to another. It will perform "work" (power equipment, generate heat, generate cold...) when it changes from one form to another, but if you reverse the process and convert it back to it's original form, it will perform another lot of "work" during the conversion and end up back in exactly the same state as it started out from, in spite of having performed two lots of "work" during the operation.

A battery does **not** provide energy to power a circuit. Instead, what happens is that the chemical action inside the battery causes negative charges to gather at the "minus" terminal of the battery and positive charges to gather together at the "plus" terminal of the battery. These two close-together "poles" of the battery are called a "dipole" (two opposite poles near each other) and they have an effect on the Zero-Point Energy Field which is everywhere. The "Plus" pole of the battery causes a massive cluster of Zero-Point Energy Field negative charges to cluster around it. In the same way, the "Minus" pole of the battery causes a massive gathering of ZPE ("Zero-Point Energy") positive charges to gather around it. Not only do these charges gather around the poles of the battery, but an imbalance in the energy field is created and the ZPE charges continue to arrive at the poles and they radiate out in every direction in a continuous stream of incredible energy.

So, there is your shiny new battery sitting there, not connected to anything and yet it causes massive energy streams to radiate out from its terminals in every direction. We don't notice it, because the energy flows freely through us and we can't feel it and none of our conventional instruments, such as voltmeters, ammeters, oscilloscopes, etc. react to it at all.

The situation changes immediately if we connect a circuit to the battery. The circuit provides a flow path for the ZPE energy to flow along, and a significant amount of energy flows near the wires of the circuit, actually powering the circuit for a split second until it reaches the battery "pole" at the far end of the circuit. When it gets there it promptly wipes out the pole, destroying it completely. The ZPE field calms down and the energy flow ceases. But our trusty battery immediately does it all again, using it's chemical energy to create the "dipole" once more, and the imbalance of the ZPE field starts again. It is because the battery has to use it's chemical energy all the time, creating and re-creating, and re-creating it's "dipole" that it runs down and eventually ceases to be able to create the dipole any more - result: no more power in the circuit.

Sorry to spoil the illusion, but the battery never did power the circuit itself, it merely acted as channelling device for the Zero-Point Energy Field. In passing, Direct Current ("DC") is actually not a continuous current at all, but instead it is a stream of DC pulses at an incredibly high frequency - way higher than we can measure at present. The speed of the pulses is so great that it looks continuous to us, a bit like the individual still pictures which are the frames of a movie, appear to be a moving image to us if they are played one after the other at a rate of 25 per second - it looks like continuous movement to us, but in reality, it is a rapid series of still pictures.

The way that a battery "dipole" works on the Zero-Point Energy Field is rather like the way that a magnifying glass acts on sunlight. The rays of the sun get concentrated into a point, focused by the lens. You can start a fire with the lens, and it would be easy to think that the lens started the fire, when in actual fact, it is the rays of the sun that started the fire and the lens just influenced a local area of the large "field" of sunlight, raising the temperature at just one point.

While we tend to think of a "dipole" being generated by a battery, the same effect is also created by a magnet, whether an electromagnet or a permanent magnet - remember that electricity and magnetism are two faces of the same entity. It is possible, but not easy, to capture the energy streaming out from the interference with the ZPE field caused by the poles of a magnet. For example, Hans Coler managed to do this with a completely passive device which, when set up correctly, could produce electrical power, hour after hour from apparently "nothing" (well, actually, the ZPE field). Roy Meyers also did it with his patented array of magnets and zinc plates - completely passive, with no moving parts at all, no battery and no circuitry.

Patrick Kelly

Chapter 13: Doubtful Devices

This chapter covers a number of devices which either are unlikely to work, or which have too little practical information available to assist replication attempts. This selection, is of course, a matter of opinion.

Paul Baumann's "Thestatika" Machine.

This device is a perfect example of a free-energy device as it powers itself and provides kilowatts of excess mains electrical power. It is in this section, not because its operation is "doubtful" in any way, but because the design has never been fully disclosed. It was developed by the late Paul Baumann who was part of a Swiss commune which is not willing to explain its operation. This "Thestatika" or "Testatika" machine works beautifully and has a very high quality of workmanship. It has two electrostatic discs which are initially rotated by hand and which then continue to rotate driven by the power produced by the device.

There are various ideas as to how the device operates. The Swiss commune no longer shows this device to people as they have the theory that "mankind" is not ready to have, or use free-energy. They have always refused to show what is inside the large cylinders mounted on each side of the device. D. A. Kelly's 1991 document provides some very perceptive comments on this device. He says:

The "Swiss M-L Converter" is a fully symmetrical, influence-type energy converter which is essentially based on the Wimshurst electrostatic generator with its twin counter-rotating discs where metallic foil sectors generate and carry small charges of electricity to be stored in matched capacitors. In Wimshurst units, diagonal neutralising brushes on each opposite disc distribute the correct charges to the sectors as they revolve, but in the M-L converter this is carried out by a crystal diode which has a higher efficiency.

Two brushes collect the accumulating charges and conduct them to the storage capacitor located at the top of this device. The device has two horseshoe magnets with matched coils and a hollow cylindrical magnet as part of the diode function, and two Leyden jars which apparently serve as the final capacitor function for the converter. The use of top grade components such as gold-plated contacts, control electrodes and dual capacitor stages, insure much higher conversion efficiencies than those available with a Wimshurst machine. The details of the operating prototype are:

1. Efficiency: The unit is started by hand and no other input power is required.
2. Constant power output: 300 volts at 10 amps = 3 kilowatts.
3. Dimensions: 43.31" (1100 mm) wide, 23.62" (600 mm) tall, 17.72" (450 mm) deep.
4. Weight: 44 lbs (20 Kg).
5. Operating speed: 60 rpm. (low speed - one revolution per second).

The twin discs are made of acrylic (plastic) and the metallic segments are steel, which causes the Searle Effect with electromagnetic conversion made at the rim of the discs through passive electromagnets. This is an ideal converter since both high voltage AC and moderate AC amperage can be generated simultaneously via two separate electrical circuits from the discs. The conventional conductive brushes pick off the high voltage AC while the rim electromagnet coils produce useful amperage. When permanent horseshoe magnets with coils are used, then the output power is enhanced to a considerable extent as shown by the above output specifications.

The self-propulsion after hand-starting the discs is achieved through the adoption of the Poggendorff principle (a German scientist of the 1870s) in which slanted conductive brushes produce self-rotation in electrostatic motors (not generators).

The special crystal diode module probably provides the dual functions of frequency regulation and capacitance amplifier - to the two Leyden jars - as part of the electrical resonance circuit, since it is connected with the horseshoe magnet coils.

This device is comprised of three separate electrical circuits:

1. The high voltage AC output from the twin electrostatic discs.
2. A moderate AC amperage circuit provided by the dual horseshoe magnet coils (Searle Effect) as the plus and minus discs pass by them. (Pulsed DC output at 50 Hz).
3. A resonant circuit in which the horseshoe magnet coils are connected to the diode capacitor so that frequency regulation is assured. The diode capacitor is then connected to the Leyden jar, transmitter unit.

The major physical principles involved in this outstanding composite unit are:

1. Electrostatic conversion using twin discs for positive output from one and negative output from the other.
2. The evidence of the Searle Effect from the use of multiple, identical steel segments inducing an EMF in electromagnets at the rim of the discs.
3. The Ecklin principle is also in evidence, since the steel segments pass by permanent horseshoe magnets, as in Ecklin's S.A.G. units.
4. The Poggendorff self-rotating electrostatic motor principle as described above.
5. The crystal capacitance function of the crystal diode module. The full operation of this unique component with its hollow cylindrical permanent magnet, is a composite component with the dual functions of distributing the correct charges to the sectors, and maintaining the output frequency at the desired value.

The M-L Converter is completely symmetrical with two acrylic discs, a light metal lattice, insulated copper wires, a secret crystal-diode rectifier, and gold-plated electrical connections. These machines have been developed over a period of twenty years.

In electrostatic generators, the air molecules between the two acrylic discs which counter-rotate closely side by side, become electrically activated by friction. This causes the discs to be continually charged until a flashover equalises the charge on them. To limit the voltage to the desired amount, the positively charged

particles on one of the discs and the negatively charged particles on the other disc are each extracted by means of separately adjustable lattice-electrodes, and are fed into a Leyden jar which collects the energy. The speed of the discs which have 50 lattice electrodes, is 60 rpm which produces a 50 Hz pulsed DC output. This speed is synchronised by magnetic impulses.

The unit is hand started by revolving the two discs in opposite directions until the Converter is charged up enough to synchronise itself and continues to rotate smoothly and noiselessly without any external source of input power. A centrally mounted disc of about 4" (100 mm) in diameter glimmers with all the colours of the rainbow. After a few seconds the Leyden jars are ready for operation and 300 volts DC with a current of 10 amps can be drawn from the device for any desired length of time. On many occasions, demonstrations have been made of the power available from the device. Heating elements, lights and hand power tools can be run from the device.

This suggested explanation of the M-L Converter contains a number of very interesting points. It has seemed mysterious that the electrostatic discs continued to rotate on their own without any visible motor driving them. Mr Kelly, who has seen the device and its operation, suggests that there are sloping brushes pressing against the front and rear faces of the twin electrostatic discs and that these are supplied with electrical current from the horseshoe magnet coils and that acts as a motor which drives the discs onwards once they have been started. He also suggests that the fifty steel segments per second which pass between the poles of the horseshoe magnets cause a rapidly fluctuating magnetic field through the magnet coils, which makes them operate as an Ecklin electrical generator, as described elsewhere in this eBook.

Mr D. A. Kelly also suggests that the two cylinders seen on the M-L Converter, are Leyden jar capacitors and that they work together as described by Sir Oliver Lodge (whose book is on this website). This is a very interesting suggestion, but it does not explain why the people in the Swiss commune refuse point-blank to let anyone see what is inside those cylinders.

There is a video produced by Don Kelly (presumably, a different person) which puts forward another theory of operation. He suggests that each of the cylinders contains a bi-filar coil on a barium ferrite magnet:

However, he describes the barium ferrite magnet as being the same type as used in radio receivers, and they are standard "ferrite rods" which are not permanent magnets as far as I am aware. Don suggests that the output from the high-voltage electrostatic discs gets fed directly to these coils and then on via a series connection to the coils around the horseshoe magnets. He envisages the bi-filar coil amplifying the current and the electrostatic discs being rotated by a standard low-voltage DC motor.

Another possibility is that the jars also contain a spark gap and surrounding copper pick-up shells and as the machine operates silently, the jars have a vacuum inside them. That would provide silent operation and explain why the people in the commune could not open them for inspection. It seems very clear that we just don't know exactly how this device operates.

One very interesting fact which has been reported by the Swiss group is that if a series of copper, aluminium and Perspex sheets are placed in a magnetic field, they generate a high voltage. This is worth investigating. It is not clear if the magnetic field should be constant or oscillating. The sequence of plates is said to be: cpacpacpacpa ("c" being copper, "p" being 'Perspex' (acrylic or 'Plexiglas') and "a" being aluminium).

The following set-up might be worth investigating:

There is good information on the Testatika at <http://peswiki.com/index.php/PowerPedia:Testatika> but unfortunately, the bottom line is that nobody knows how to replicate Paul Baumann's excellent machine.

If you wish to understand the operation of electrostatic discs, then the McGraw-Hill book "Homemade Lightning" by R.A. Ford (ISBN 0-07-021528-6) gives full details of Wimshurst machines and plans for constructing your own, improved version. Ready-built Wimshurst machines are available from the web site: <http://scientificsonline.com/product.asp?pn=3070070&bhcd2=1154180654>

The Homopolar or "N-Machine".

This device was the brainchild of Michael Faraday in 1831 and has an intriguing method of operation and a remarkably large output.

The principle of operation is incredibly simple:

If a copper disc is rotated in a magnetic field, then power is developed between the shaft and the outer edge (or any intermediate position). It was then found that the device will still operate even if the magnet is attached to the copper disc and rotates with it - not something which is intuitively obvious. The power output is tremendous with the capability of extracting 1000 Amps but at a low voltage of less than 1 Volt. The power take-off can be from one face of the disc near the shaft rather than having to have a copper shaft integral with the copper disc. This device also works with a magnet just attached to the copper disc and rotating with it.

This looks like a very viable starting point to develop a device which can run itself and provide useful additional output, since a motor to rotate the disc will not require anything remotely like 1000A to drive it. The snag is, it is very difficult to provide reliable sliding contacts capable of handling large currents for extended periods of time. The second picture above shows the disc with its outer edge immersed in a bath of mercury. This is sufficient for a brief demonstration at low power but not realistic for a serious working device.

It might just be possible to get a reasonable working device by accepting that the current output is not going to be anything like 1000A. Long-life brushes could be made from solid copper bar and spring-loaded against the copper disc in matching pairs so that the brush thrusts oppose each other and so do not generate a sideways load. These could be made in multiple sets for each disc, say four or eight per disc, so that the effective electrical resistance between the brushes and the disc is reduced and the possible current draw increased.

Similar multiple brushes could be applied to the central shaft cylinder. Multiple discs could then be mounted on a non-conducting, non-magnetic shaft and their brushes wired in series as shown, to raise the output voltage:

However, when this is done, the brush drag is a serious problem. In 1987, three of the Borderlands Science team, Michael Know, Peter Lindemann, and Chris Carson experimented with this design and found that a much more satisfactory version could be produced. Their version produces sawtooth AC instead of DC and so the output could be fed directly into a step-up transformer. Their design has four ferrite magnets glued between two metal discs, and for additional mechanical strength, copper wire wound around the outer edges of the magnets in order to prevent magnets flying outwards if the glue bond should fail. Their arrangement is like this:

This appears to contradict the “laws” of conventional electricity as there is a very low resistance short-circuit directly across the brushes which pick up the AC voltage output. The output current from a small prototype was estimated at 100 amps. The frequency of the AC is directly proportional to the shaft speed of the motor, **but** the output voltage was almost independent of the shaft speed of the motor, increasing only very slightly with much greater speed. It was also found that putting the brushes at 90 degrees apart on the metal shaft of the motor gave the same output in spite of the contacts nearly touching each other. This design appears to have considerable potential for construction in a larger size and further investigation.

While the operation of these devices looks impossible at first glance, it needs to be understood that copper has some very unusual characteristics when interacting with magnetic fields. This is explained in the web site <http://magnetism.vfedtec.com/SpinningCylinder.htm> where it can be seen that a spinning copper cylinder exerts a large sideways force on a permanent magnet placed near it. This does not happen with spinning cylinders made from other metals.

Paramahansa Tewari received an Indian patent (397/Bom/94) in 1994 for a COP=2.5 version, details of which can be seen at <http://www.rexresearch.com/tewari/tewari.htm>.

The ‘Romag’ and ‘Mini-Romag’ Generators.

These generators have been displayed on the internet for some considerable time now. They can be found on the Jean-Louis Naudin website:

<http://jnaudin.free.fr/html/mromag.htm>

The Mini Romag generator from Magnetic Energy uses the principle of moving magnetic flow named "the magnetic current" for generating electrical power. According to Magnetic Energy this generator is able to produce 3.5 volts, 7A DC (24 Watts) of free electricity plus sufficient power to sustain itself.

This generator needs to be started by using an external motor to rotate it at 2,100 rpm for some 42 seconds. After this, the energy flow is established in the Romag generator and the external motor can be removed and the free electrical energy output can be used.

The starting procedure generates magnetic energy within the six coils of copper wire, the copper tube supporting these coils and the copper coated steel wires wrapped around the magnets. This charging is accomplished while the six coil connection wires, (shown as 22 in the above drawing), are making contact and setting up their alternating magnetic poles. After the 42 second start-up time one of these coil connection wires is opened by switch (24 above) leaving the working load in its place. The load (23 above) can draw 7 amps. As current is drawn from the six coils, it sets up magnetic poles which react with the rotor magnets maintaining the rotation. The main shaft is rotated by the 12 permanent magnets as they attract and build a release field. Then the driver unit (hand crank or motor) is disconnected allowing the unit to continue rotating with the load being the **activating** driving force.

Construction:

If you decide to attempt to build one of these units we suggest using the stated materials:

1. Aluminium Base Plate
2. Sleeve Bearing of oil impregnated brass, 1" long, 0.5" inside diameter.
3. Brass Shaft, 4" long, 0.5" outside diameter
4. Rotor, brass 1.75" long, 2" diameter,
5. Six rotor slots, each 1.75" long, 0.26" deep, 0.72" wide. These slots are spaced exactly 60 degrees apart.

6. One slot cut in centre of Brass Rotor, 360 degrees around, 0.25" wide by 0.313" deep.
7. 12 slots (produced from the six slots when the 360 degree cut is made). Each slot is lined with mica insulation, 0.01" thick.
8. A total of 228 pieces of U-shaped copper coated steel wires, 0.04" thick. Each slot (7 above) has 19 pieces of these wires fitted into the Mica, thus these wires do not contact the Brass rotor. The leading edge of these wires is flush with the Rotor's outer surface and the trailing edge protrudes 1/8" above the Rotor's outer diameter.
9. Each of the 12 magnets receives eleven complete turns of 0.032" thick copper coated steel wire. These 11 turns or 'wraps' accumulate to 3/8" wide and the same pattern is placed around all 12 magnets. When placed into the bent wires (8 above), they form a snug fit making firm contact.
10. Twelve pieces of mylar insulation, 0.005" thick, are inserted into the cores of the wires (9 above).
11. The twelve permanent magnets, insulated with the mylar, must not contact wires of 9). These magnets measure 3/4" long, 5/8" wide, 3/8" thick and are made of a special composition and strength. Alnico 4, M-60; 12 AL, 28 Ni, 5 Cobalt Fe, Isotropic permanent magnet material cooled in magnetic field, Cast 9100 TS. 450 Brin, 2.2 Peak energy product. When inserted in the rotor the outer faces of these 12 magnets are not to be machined to a radius. The centre of these magnets pass the centre of the coils with 3/32" clearance. The edges, where the wires are wrapped, pass 1/32" away from the coils. This 'changing magnet spacing' aids in not only the release cycle but also contributes to rotational movement. (Sharp magnet edges which are facing the coils are to be sanded to a small smooth radius.)
12. Make sure that the magnets are placed in the Rotor with the polarity shown in the diagram.
13. The 12 magnet wire wraps are divided into two sections; 6 upper and 6 lower. There are no connections between these sections. The magnetic flow direction between the upper 6 wraps and the lower 6 wraps is attained by the 'flow direction'. The wires are wrapped around the magnet starting at the top 'north' half and then after 11 complete turns the wire exits at the lower 'south' half. As this wire then goes to the next magnet it arrives at an attract wire which is its 'north' side. Thus all wires get interconnected from south to north magnet half or north to south magnet half. The actual connections should be crimped copper clips (**not** solder) with insulation tubing to prevent contact to the Rotor body.
14. A 0.03" thick copper tube (stiff material) 2" long by 2½" inside diameter.
15. Six slots are cut at the top of tube #14. These slots are 5/8" wide by 1/32" deep spaced at 60 degrees apart.
16. Six slots are cut at the bottom of tube #14. These slots are 5/8" wide by 5/16" deep and in line with the upper slots #15.
17. There are six copper tube mounting points.
18. An acrylic ring is used to hold Part #14, measuring 3.75" outer diameter and 2.25" inner diameter, 3/8" thick, bolted directly to Part #1. This ring has a 0.03" wide groove cut 0.25" deep to allow the six copper tube mounting points to be inserted (part 17).
19. Plastic insulation paper, 0.002" thick, is to be placed around the inside and outside of Part #14.
20. There are six coils of insulated copper wire, each coil having 72 turns of .014 thick wire. Each coil is wound with two layers, the bottom layer completely fills the 5/8" wide slot with 45 turns and the top layer spans 5/16" wide with 27 turns. To be sure each coil has the exact wire length of 72 turns, a sample length wire is wrapped then unwound to serve as a template for six lengths. A suggested coil winding method is to fill a small spool with one length then by holding the copper tube at the lower extension, then start at the plus wire in Figure 2 and temporarily secure this wire to the outer surface of the tube.
21. Next, place the pre-measured spool of wire inside the tube, wrapping down and around the outside advancing clockwise until the 5/8" slot is filled with 45 turns. Then, return this wire back across the top of the coil for 15/32" and winding in the same direction again advance clockwise placing the second layer spanned for 5/16" with 27 turns. This method should have the second layer perfectly centered above the first layer. After winding this coil, repeat the process, filling the small spool with another length of pre-measured wire. A very important magnetic response happens as all six coils have their second layers spaced in this way.
22. Item 22 above shows the connection pattern for six coils. When the unit is driven at start-up (hand crank) for 42 seconds at 2100 RPM, all six jumper wires must be together which means the plus wire goes to the minus wire connected by the start switch. After 42 seconds the load is added to the circuit and the start switch is opened. To double check your connections between the coils, note that the finish wire of coil #1 goes to the finish wire of coil #2, which is top layer to top layer. This pattern then has start of coil 2 (bottom layer) going to start of coil 3 (also bottom layer). When the copper tube with the coils is placed around the rotor, the distance from any magnet to any coil must be identical. If it measures different, acrylic holding shapes can be bolted to the aluminium base, protruding upward, and thus push the copper tube in the direction needed to maintain the spacing as stated.
23. Wires to load.
24. Wires to start switch.
25. Rotational direction which is clock—wise when viewing from top down.
26. Acrylic dome for protection against elements.

27. Coating of clear acrylic to solidify rotor. **Do not use standard motor varnish.** Pre-heat the rotor and then dip it into heated liquid acrylic. After removal from dip tank, hand rotate until the acrylic hardens, then balance rotor. For balancing procedure, either add brass weights or remove brass as needed by drilling small holes into rotor on its heavy side.
28. Insulation tubing on all connections.
29. Shaft for start purposes and speed testing (if desired).

The reason that this generator is included in this chapter is because the construction is quite complex. Also, the plans have been around for several years without my being aware of anyone constructing or operating one of these units other than J.L. Naudin.

Cold Fusion.

Cold fusion was initially accepted with great excitement. It then appeared to be discredited, primarily as a matter of fear of losing the funding for the decades old "hot" fusion research. At the present time, there are some two hundred labs. which have confirmed the findings and so there is no doubt as to the reality of the system. In essence, it is said that nuclear fusion can take place at room temperature, under certain conditions. However, a commercial working device is now reaching the market with details at Sterling Allan's website: [http://peswiki.com/index.php/Directory:Andrea A. Rossi Cold Fusion Generator](http://peswiki.com/index.php/Directory:Andrea_A._Rossi_Cold_Fusion_Generator).

If you want the background details of cold fusion history, then there are several web sites which follow the progress in this field, including "Cold Fusion Times" at <http://world.std.com/~mica/cft.html> where considerable detail is available. However, although a cold fusion generator is unlikely to be something which you can knock together in your back yard, the process is edging steadily towards general use. In 2012, the Rossi "Ecat" cold fusion generator is expected to launch. The web site <http://ecat.com/> is already taking orders and the home unit producing 10 kilowatts, is expected to sell for US \$500 and have an annual running cost of just \$20.

The Frolov / Moller Atomic Hydrogen Generator.

One already successful experiment has been shown at the J.L. Naudin website where many successful tests were performed. Alexander Frolov remarks that due to the water pump being externally powered, the results shown by J.L. Naudin are not quite accurate although the error is not significant for power levels below one kilowatt, and so the performance is actually very slightly less than that reported.

This system started with William Lyne's concept which he published in his book "Occult Ether Systems" in 1997. In 1999, Nikolas Moller bought a copy of Lyne's book and drew the attention of Alexander Frolov to the idea. Alexander then worked on the idea and produced both the present theory and design. A joint project was then started between Alexander's Faraday Company Ltd. of St. Petersburg in Russia (www.faraday.ru) and Nikolas' company Spectrum Ltd.

The prototype shown in the photograph below, was then built by Alexander and passed to Nikolas where it was tested extensively. The exact process involved in the energy gain has only recently been fully disclosed in Alexander's book entitled "New Energy Sources".

The technique used involves repeatedly converting a quantity of hydrogen gas from its diatomic state (H_2 where two hydrogen atoms are bonded together to form a stable molecule), to its monatomic state H (where two hydrogen atoms remain as separate atoms, not closely bonded together) and back again to its original form.

No hydrogen is consumed. No additional gas is required. The gas is just converted from one state to the other, repeatedly. The problem for conventional science is that the output power measured in tests is considerably greater than the input power in carefully measured tests which were run for periods of more than half an hour each. The additional power is flowing in from the Zero-Point Energy field due to an energy extraction mechanism caused by the collision of molecules which have very different atomic weights. This is explained by Dr Frolov in his paper: <http://alexfrolov.narod.ru/mac.html> where the energy imbalance is described in detail. In it, he observes that the theory shows clearly that an input of 1,400 watts is capable of producing an output of 7,250 watts due to the impact energy imbalance between high-mass and low-mass molecules when they collide.

Here is a photograph of the development assembly built by Alexander Frolov and then used in the testing phase of the system:

Muammer Yildiz's "Ocean Star" Electrical Generator.

This is a purely mechanical device which is self-powered and which can provide electric current to drive other equipment. This device was designed and built in Turkey. It was demonstrated in Dortmund on 17th October 2005 where the demonstration was conducted by J. L. Duarte who ran an independent test and produced a report dated 17th July 2005 on behalf of the Department of Electrical Engineering, Electromechanics and Power Electronics of the Eindhoven Technische Universiteit. Muammer has obtained Patent Application WO2004091083 for his design. The demonstration was of his portable unit which outputs some 12 volts DC:

During the demonstration was used to light a car light bulb very brightly:

Muammer has also produced a larger version capable of powering a house:

The demonstration unit was started using a 16 AHr battery for a few seconds. Once the unit reaches its running speed, it becomes self-powered and capable of delivering substantial electrical power and the starting battery is then disconnected. In theory, no mechanical system can produce 100% efficiency, let

alone more than 100%. This system where a motor spins several generators, is very much like the Raoul Hatem system described in Chapter 2.

The report by Dr. J. L. Duarte on the smaller unit provides the following information:

This technical note aims at describing a test which I personally conducted in Izmir, Turkey on 17th July 2005. The purpose of the experiment was to check the energy balance with respect to input and output of an apparatus which was the embodiment of the invention described in the international patent WO 2004/091083 A1 (shown below).

The apparatus was confined inside a metallic box sized 550 x 380 x 270 mm, weighing some 20 Kg, and I was allowed to inspect everything outside this box. However, in order to protect the core ideas of the invention, I was not supposed to check all the details of the internal parts. According to the inventor, the apparatus is predominantly a mechanical system, without any kind of energy storage inside the box (such as batteries, accumulators, flywheels, combustion motors, chemical or radioactive reactions). I believe the intentions of the inventor to be in good faith.

The experimental set-up was quite simple, as shown schematically in **Fig.1**. It consisted of placing the box with unknown contents, from which DC voltages and currents were expected to be generated, on a table in the middle of the room. A cable with two terminal contacts was run from the box and instruments were placed between the box and the load, which was a standard DC/AC inverter driving an incandescent lamp. The output power from the box was measured before the load connection as shown here:

The circuit connection method used is shown here:

After a short start procedure, the metallic box and the load were both fully isolated from the environment, ensuring that there was no physical contact or connection to external power sources such as the public electric mains supply, at any time during the whole duration of the measurements. As the start-up energy input to the apparatus was quite modest, the main issue was then to measure the delivered energy output.

I had prepared the power measurements with care, by using reliable instruments which I personally brought with me from my own University laboratory. In order to measure the DC voltage directly out of the positive

and negative terminals, I used two different voltmeters connected in parallel. One voltmeter was an analogue type, constructed with permanent magnets and wires, while the other was a digital voltmeter. To measure the DC current I used two ammeters in series, one analogue and one digital. If electromagnetic waves should interfere with the measurements, then they would disturb one or other instrument, but not all four pieces at the same time and in the same way.

Before starting the test, no audible sound was being produced by the apparatus. The measured voltage and current at the terminals were zero. So, as far as I could observe, the apparatus was completely at rest.

The start-up procedure consisted of connecting a small 12V DC lead-acid battery to two contact points inside the box for a few seconds. I checked the time using my own watch and it was more than 5 seconds but less than 10 seconds. I consider it reasonable to consider the time to have been 8 seconds. After that time, no energy input was connected to the box by means of cables.

Immediately after the start-up procedure, I could hear noise such as would be produced by parts rotating inside the box. The inventor said that some ten minutes should be allowed to elapse before the load was connected. During that time, both of the voltmeters showed the output voltage dropping slowly from 12.9 volts to 12.5 volts. The two voltmeters matched accurately. In the following hours, I observed and recorded by hand, the voltage and current values displayed by the instruments. The displayed values were quite stable, so I initially decided to note them at 15 minute intervals, but later on at 30 minute intervals.

From time to time, using my hands, I attempted to find a temperature gradient inside the box, but I could not detect any variation or increase in the temperature compared to the room temperature. After five hours, I took the decision to stop the measurements. The results are shown in the following table:

Time	V1 (Digital)	V2 (Analogue)	A1 (Digital)	A2 (Analogue)
0:00	12:54	12.5	2.23	2.35
0:15	12.57	12.5	2.29	2.35
0:30	12.57	12.5	2.29	2.35
0:45	12.53	12.5	2.27	2.35
1:00	12.51	12.5	2.27	2.35
1:15	12.48	12.5	2.27	2.35
1:30	12.47	12.5	2.27	2.35
2:00	12.41	12.4	2.26	2.35
2:30	12.35	12.4	2.26	2.35
3:00	12.30	12.3	2.25	2.35
3:30	12.22	12.3	2.25	2.3
4:00	12.15	12.2	2.25	2.3
4:30	12.01	12.1	2.24	2.3
5:00	12.00	12.0	2.23	2.3

As far as I am concerned, the above table of results raises serious doubts. The voltage readings are absolutely typical of an inverter powered by a lead-acid battery. I have tested many batteries in exactly the same way and the table looks 100% familiar. If the box contained a genuine self-powered generator, then I would expect the output voltage to remain constant under the constant current drain. In my opinion, it was wholly irresponsible to have stopped the test after just five hours with the output voltage falling steadily. If the output voltage had been rock steady at 12.5 volts for the whole five hours, then that would not have been quite so bad but with it going down 12.3, 12.2, 12.1, 12.0 in the last four 30-minute intervals, and with a lead-acid battery voltage of 11.5 for a fully discharged battery, it was wholly unrealistic to stop the test. A further ten hours of testing should have been undertaken.

However, early in 2010, Muammer demonstrated a permanent magnet motor/generator of his own design. That type of device is notoriously difficult to get functional, let alone producing the 250 watts of power which Muammer demonstrated at Delft University. As part of the demonstration, Muammer took the motor apart completely to show that there was no hidden power source. This shows clearly that Muammer is a man of very considerable ability, and that lends considerable credibility to his earlier device shown here. Unfortunately, the patent application is not in English and some of the terms produced by a rough translation are not at all clear. Consequently, although the design appears quite simple, it can't be rated as a design which could be confidently replicated from the information here and for that reason, the OceanStar information remains here, among the "Unlikely to Result in a Workable Device" section.

Here is the information from the Patent Application WO2004091083 although the quality of reproduction and the clarity of the wording is not particularly good:

A SYSTEM WHICH GENERATES ELECTRICAL POWER VIA AN ACCUMULATOR THAT PROVIDES THE INITIAL MOTION FOR THE SYSTEM

ABSTRACT

This is a portable system that generates electrical power via an accumulator that provides the initial motion for the system. Two batteries are used in this system and the system is kept working via the initial motion provided by these batteries. There is no need for another transformer. This device works using its own mechanism and there is no need for additional devices. In this way, a continuous electrical power generation is possible. This device can work without connecting it to a network so it is possible to use it at places where electricity does not exist. Moreover, when connected to the entry of a building, the need for a network is avoided. This system generates electrical power independent of a network.

DESCRIPTION

A system which generates electrical power via an accumulator that provides the initial motion for the system. This is a portable system that generates electrical power via an accumulator that provides the initial motion for the system. Already existing systems can generate electric power of whose duration depends on the lifetime of the battery. In these systems, the battery has to be reloaded in order to restart the system. 12V electrical power provided by the batteries used in cars is increased to 220 V via transformers.

Two accumulators are used in our invention. The system works on a continuous basis after the initial start up via these accumulators. There is no need for another transformer. Our system, which generates electrical power, does not need any other devices and it keeps on generating energy via its own mechanism. Also, the system works without connecting it to a network.

Thus, it can be used at any place where no electricity exists. Nevertheless, when this system is connected to the entry of the buildings, there is no need for an additional network. The system can produce electrical power independent of a network.

DESCRIPTION OF THE DRAWINGS

Below are the explanations of the figures that provide a better understanding about this invention.

Fig.1 is a schematic view of the system.

Numbers used on the schematic:

1- Accumulator

- 2- Regulator
- 3- Big Gear 3/1-Starter dynamo
- 4- Small gear 4/1-2-Feedback dynamo
- 5- Small gear 5/1-2-3-Feedback dynamo
- 6- Contactor
- 7/1 and 7/2- Commutator
- 8- 29 DC input
- 9- 24 DC output
- 10- 580 DC output
- 11-Switch
- 12- Shunt
- 13- Rectifier
- 14- Capacitor
- 15- 2.5 mm cable
- 16- Collector
- 17- Charcoal
- 18- Fixing clamps
- 19- Fixing clamps
- 20- Lamp
- 21- Conjector
- 22- Starter dynamo
- 23- Feedback dynamo
- 24- Alternating current dynamo
- 25- Magnetic switch
- 26- Pulley
- 27- Pulley
- 28- V pulley
- 29- 380V current output
- 30- 220 V current input

Figure 2

DESCRIPTION

This invention is a system that starts working via the motion of alternator. There exist two accumulators(1), and the first motion provided by the accumulator is carried to the regulator. Contactor (6) keeps the starter dynamo working by disconnecting the accumulator (1) once the regulator (2) is put in. The voltage coming from the accumulator (1) passes through the regulator and the start dynamo (3/1) starts working and thus the feedback alternators via the gears (4/1-2-5/1-23-3). Feedback dynamo start sending pure DC current to regulator via shunt (12), capacitor (14) and diode (13). It connects all the currents that reaches to the regulator in 4 seconds and sends to the contactor (6). Accumulator (1) is put out by this current that reaches to the regulator. This current is transformed to the started dynamo (3/1). There becomes a transformation within the system. In case of electricity shortage, it keeps on working by using the current generated by the commutatoris (7/1).

Via the starter dynamo(3/1), DC is generated in the alternators which are connected to the gears and this current is transformed to the commutatoris (7/1 and 7/2) and DC voltage is generated at commutatoris (7/1 and 7/2).

Second System: 3x24 DC voltage is transformed to the second starter dynamo (22). Once the start dynamo works (22), a feedback dynamo (23) having a pulley system and a feedback dynamo (24) generating alternating current starts working. The feedback dynamo (23) starts feeding back; the feedback dynamo (24) which generates alternating current is independently generating 6 KV, 18 Amp, 50Hz current. Moreover, first system produces 24 DC and 580 DC current on its own. The bigger the gears are, the more the generated current is.

This system, which is the subject of our invention, can be used at any place. You can use it at places where there exist no electricity, or at places such as villages, cities, buildings, greenhouses where there is no network. Moreover, network is no longer a must. Instead of a network, you can use our system. There is no need for gasoline when this system is used in vehicles.

Jesse McQueen's System.

There is a US patent which was granted to Jesse McQueen in 2006. This system looks too good to be true and, on the surface, appears impossible, even taking into account that it has been said that ordinary vehicle alternators have a Coefficient Of Performance over one (i.e. output energy is greater than the energy that the user has to put into the device to make it operate). I am not aware of anybody who has tried this system, so I have no evidence that it doesn't work - just a lack of belief in a system of this type being able to operate as described. As against that, it is not far from the proven system of Chas Campbell (chapter 4) and the US Patent office has granted this patent and they have a reputation of being highly opposed to admitting that there is any such thing as a "perpetual motion machine", which this system appears to be. So, I leave it up to you to make up your own mind, and test the system if you wish, which should be easy to do as it involves no real construction, but instead, uses off-the-shelf manufactured products which are readily available and not particularly expensive. Here is the patent:

US Patent 7,095,126

22nd August 2006

Inventor: Jesse McQueen

INTERNAL ENERGY-GENERATING POWER SOURCE

ABSTRACT

An external power source such as a battery is used to initially supply power to start an alternator and generator. Once the system has started it is not necessary for the battery to supply power to the system. The battery can then be disconnected. The alternator and electric motor work in combination to generator electrical power. The alternator supplies this electrical power to the two inverters. One inverter outputs part of it's power to the lamp, and part back to the electric motor/generator. This power is used to power the electric motor. The second inverter supplies power to the specific load devices which are connected to the system.

BACKGROUND OF THE INVENTION

Electrical energy occurs naturally, but seldom in forms that can be used. For example, although the energy dissipated as lightning exceeds the world's demand for electricity by a large factor, lightning has not been put to practical use because of its unpredictability and other problems. Generally, practical electric-power-generating systems convert the mechanical energy of moving parts into electrical energy. While systems that operate without a mechanical step do exist, they are at present either excessively inefficient or expensive because of a dependence on elaborate technology. While some electric plants derive mechanical energy from moving water (hydroelectric power), the vast majority derives it from heat engines in which the working substance is steam. Roughly 89% of power in the United States is generated this way. The steam is generated with heat from combustion of fossil fuels or from nuclear fission.

In electricity, a machine is used to change mechanical energy into electrical energy. It operates on the principle of electromagnetic induction. When a conductor passes through a magnetic field, a voltage is induced across the ends of the conductor. The generator is simply a mechanical arrangement for moving the conductor and leading the current produced by the voltage to an external circuit, where it actuates devices which require electricity. In the simplest form of generator, the conductor is an open coil of wire rotating between the poles of a permanent magnet. During a single rotation, one side of the coil passes through the magnetic field first in one direction and then in the other, so that the induced current is alternating current (AC), moving first in one direction, then in the other. Each end of the coil is attached to a separate metal slip ring that rotates with the coil. Brushes that rest on the slip rings are attached to the external circuit. Thus the current flows from the coil to the slip rings, then through the brushes to the external circuit. In order to obtain direct current (DC), i.e., current that flows in only one direction, a commutator is used in place of slip rings.

A commutator is a single slip ring split into left and right halves that are insulated from each other and are attached to opposite ends of the coil. It allows current to leave the generator through the brushes in only one direction. This current pulsates, going from no flow to maximum flow and back again to no flow. A practical DC generator, with many coils and with many segments in the commutator, gives a steadier current. There are also several magnets in a practical generator. In any generator, the whole assembly carrying the coils is called the armature, or rotor, while the stationary parts constitute the stator. Except in the case of the magneto, which uses permanent magnets, AC and DC generators use electromagnets. Field current for the electromagnets is most often DC from an external source. The term dynamo is often used for the DC generator; the generator in automotive applications is usually a dynamo. An AC generator is called an alternator. To ease various construction problems, alternators have a stationary armature and rotating electromagnets. Most alternators produce a polyphase AC, a complex type of current that provides a smoother power flow than does simple AC. By far the greatest amount of electricity for industrial and civilian use comes from large AC generators driven by steam turbines.

SUMMARY OF THE INVENTION

It is an objective of the present invention to provide an energy source that generates more energy than the energy source requires in order to operate.

It is a second objective of the present invention to provide a system that uses the excess energy produced by the energy source to power other various devices.

It is a third objective of the present invention to provide an energy source for supplying power to various devices without the reliance on an external energy source for supplying power to the energy source of the present invention.

The present invention provides an energy source that is capable of producing more energy than it requires to operate. The excess energy is used to power devices. A feedback loop approach is used to channel a portion of the energy produce by the generator back to the generators power input port. This feedback loop approach enables the generator to use its own generated energy to operate. The additional energy generated by the generator is used to power other devices that can be connected to the generator.

In the method of the invention an external power source such as a battery is used to initially supply power to start an alternator and generator. Once the system has started it is not necessary for the battery to supply power to the system. The battery can then be disconnected. The alternator and electric motor work in combination to generate electrical power. The alternator supplies this electrical power to the two inverters. One inverter outputs part of its power to the lamp load device and part back to the electric motor/generator.

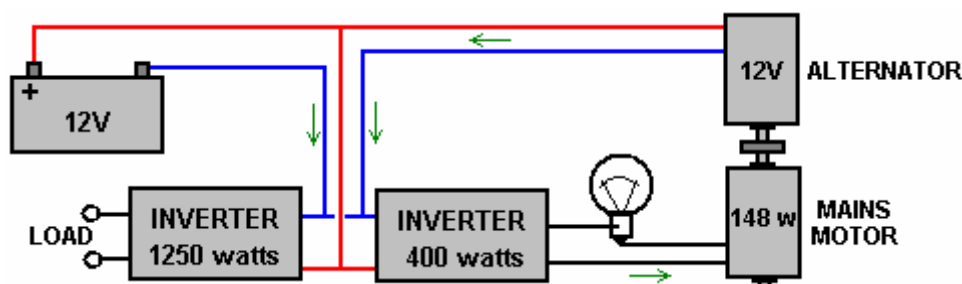

This power is used to power the electric motor. The second inverter supplies power to the specific load devices that are connected to the system.

DESCRIPTION OF THE DRAWINGS

Fig.1 is a configuration of an implementation of the internal power generating system of the present invention.

Fig.2 is a configuration of an alternate embodiment of the internal power generating system of the present invention.

DESCRIPTION OF THE INVENTION

This invention is an electric power-generating device that produces several times more power than it takes to operate this system. This invention comprises a first power source that is connected to a second power source. Referring to **Fig.1**, the system of the present invention comprises a battery source **10** (12 volt DC) that connects to an electrical alternator **20**. The battery supplies the initial power to the system to initiate/start the operation of the alternator. The present invention can implement other power sources in addition to the illustrated battery to supply the initial power to the system. In the initial model of the present invention incorporated an alternator from a 1997 Isuzu Trooper. The invention incorporates an electric motor **30** (148 watt AC). The electric motor connects to an inverter **40** (400 watt AC). The system also comprises a second inverter **50**. The battery **10** also connects to both inverters **40** and **50**. Each inverter has two outputs. For the first inverter **40**, one output feeds into the electric motor **30** to provide to the motor and alternator combination. The other output feeds into a lamp device **60**. The lamp device is a 60-watt AC lamp. This lamp device alters the current travelling from the inverter **40** such that the current feeding into the electric motor **30** is not purely inductive.

Although, **Fig.1** shows a lamp device, other loads can be used to accomplish this same a task. The inverter **40** has an input from which the inverter receives power from the alternator **20**. The second inverter **50** also has an input that also receives power from the alternator.

In operation, initially, the battery **10** is used to supply power to start the alternator **20** and generator **30**. Once the system has started, it is not necessary for the battery to supply power to the system. The battery can then be disconnected. Once started, the alternator **20** and electric motor **30** work in combination to generate electrical power. The alternator supplies this electrical power to the two inverters **40** and **50**. Inverter **40** outputs part of this power to the lamp **60** and part to the electric motor **30**. This power is used to

power the electric motor. The second inverter **50** supplies power to the specific load devices which are connected to the system. These load devices can be any devices which operate by using electrical power.

The key aspect of the present invention is the loop between the alternator **20**, electric motor **30** and the first inverter **40**. A portion of the power generated by the electric motor is recycled and is used to power the electric motor. In this way the system produces the power internally that is used to power the system. This concept makes this system a self-power generating system.

Fig.2 shows an alternative embodiment of the power generating system of the present invention. This embodiment incorporates a gear box **70**, a car starter **72**, and a head brush generator **74**, and buck booster **76**. Initially, the car starter **72** works with the battery to supply power to the generator. This process is similar to the process of starting a car. The gearshift **70** increases the rpm of the generator. The Buck Booster **76** serves as the output to supply power to the various loads. This configuration also incorporates a DC converter **78**.

The “Nitro” Cell.

This document was originally produced at the request of an Australian man who said that the cell worked well for him but that he was afraid to publish the details himself. This document was prepared, approved by him and published. It proved very popular and an enthusiast group was set up to build and test this “Nitro Cell”.

The results of this building and testing have been most unsatisfactory. As far as I am aware, not a single cell proved successful in powering an engine. I therefore, withdrew the document, since even though I believe it to be capable of working, the fact that many people failed to get it working indicates to me that this document should not be in a “practical” guide. I have been assured by two separate independent sources, both of which I rate as being reliable sources, that there are “hundreds” of these cells working in Australia and the USA. I have repeatedly been asked for copies of this document, so I am publishing it again, but requesting

you, the reader, to be aware that should you make one of these devices, that it is unlikely that you will get it operational. Having said that, I understand that it may work very well as a booster.

Simple arithmetic applied to the claimed performance of this device, shows that much of the claimed mileage has to have been covered without using any fuel at all. While this sounds impossible, in actual fact it is not, **but** that sort of operation comes from the Joe Cell which is notoriously difficult to get operational, requiring at least a week of fiddling around to get the metalwork of the vehicle aligned with the energy field used to provide the motive power. Also, each person acts as a "dipole" which produces an energy field around that person. Most people have a polarity which opposes the Joe Cell energy, and they will **never** get a Joe Cell to operate as they can disrupt such a cell from several paces away from it. Chapter 9, which describes the Joe Cell, includes information on how to reverse your own personal polarity, to stop blocking the cell performance.

This definitely sounds unbelievable, but as it happens to be the way that things actually are, there is little point in pretending otherwise. Personally, I never recommend anybody to build a Joe Cell for powering a vehicle, as the likelihood of success is so low. However, having said that, a friend of mine in the USA has his Joe Cell connected to his truck in "shandy" mode where the carburettor is left connected to it's normal fossil fuel supply. The vehicle is perfectly capable of drawing in fossil fuel to run the engine, but it just doesn't. His fuel consumption is literally zero and he is driving around powered solely by the energy channelled into the engine by the Joe Cell. This is most unusual, and I do not recommend you spending time and money on building such a cell. I mention these cells so that you can know all about them, but I would leave it at that.

Here is the original "D18" document, which is followed by important update information:

A Different Fuel

In the early days of heavier than air flight, observations were made and based on those observations, practical operating rules were deduced. After a time, those rules became called the "laws" of aerodynamics. These "laws" were applied to the design, building and use of aircraft and they were, and are, very useful.

One day it was observed that if you apply those laws of aerodynamics to bumble bees, then according to those laws, it was not possible for a bee to fly since there was just not enough lift generated to get the bee off the ground. But simple observation shows that bees do in fact fly and they can rise off the ground when they choose to do so.

Does that mean that the "laws" of aerodynamics are no good? Of course not, as they have been shown to be of great practical use when dealing with aircraft. What it did show was that the existing laws did not cover every instance, so research was done and the laws of aerodynamics were extended to include the equations for lift generated by turbulent flow. These show how a bee can develop enough lift to get off the ground. Do bees care about this? No, not at all, they just go on flying as before. What has changed is that the understanding of scientists and engineers has been extended to better fit the world around us.

Today, people who are trained in science and engineering are fed the idea that internal combustion engines need to consume a fossil fuel in order to operate. That is not strictly true and at the present time, engines using hydrogen gas as a fuel are becoming commonplace. Unfortunately, most of the hydrogen produced for this use, comes from fossil fuels, so these vehicles are still running on a fossil fuel, though only indirectly.

The "laws" of engineering say that it is not possible for an internal combustion engine to run without consuming some sort of fuel. Unfortunately, Josef Papp has demonstrated an internal combustion engine which has had it's intake and exhaust systems blanked off. Filled with a mixture of inert gasses, during one demonstration, that Volvo engine ran for half an hour, producing a measured 300 horsepower, and apparently consuming no fuel at all. Josef received US patent 3,680,432 for his engine and you can see a video of one of his engines running at <http://video.google.com/videoplay?docid=-2850891179207690407>. Robert Britt designed a similar sealed motor filled with a mixture of inert gasses, and he received US patent 3,977,191 for it.

Does this mean that the current laws of engineering are of no use? Certainly not, they are vital for everyday life today. What it does mean, however, is that the present laws need to be extended to include the effects shown by these engines.

Another thing widely accepted today is that an internal combustion engine can't use water as a fuel. Well.... let's leave that to one side for the moment and look at it from a slightly different angle. Engines can definitely

run using air and hydrogen as the fuel, there is no argument about that as there are many vehicle around which do just that. If you pass a current through water, the water breaks up into hydrogen gas and oxygen gas, this mixture is called "hydroxy" gas and that can most definitely be used, along with air, as the fuel for an internal combustion engine. But... this gas came from water, so is it really correct to say that water cannot be used as the fuel for an internal combustion engine?

Ah, says somebody with relief, that is not the case, because you are using water **and** electricity to get the fuel for the engine. But... the average vehicle powered by an internal combustion engine, has an alternator which produces electricity when the engine is running, so **there** is a source of electricity to do the electrolysis of the water and produce the gas to run the engine.

But the laws of engineering say that you can't get enough electricity from the alternator to produce enough gas to run the engine. Engineers will point to the work of Faraday who examined the process of electrolysis in great detail and produced the "laws" of electrolysis. These laws show that you can't get enough electrical power from an engine to make enough gas to run the engine.

Unfortunately, there have been several people who have done just that, so we have reached the point in time when these "laws" need to be extended to cover cases not covered by the work of Faraday. People have got from 300% to 1,200% of the gas output which Faraday considered to be the maximum possible. Several people have run vehicles on hydroxy gas produced by electrolysis of water using electricity generated by the vehicle's alternator. This shows clearly that it can be done, and as a consequence, the "laws" need to be extended to include the newer techniques.

Leaving that aside for the moment, there have been at least two people who have managed to power an engine with water as the only fuel, and without using electrolysis. In this instance, a fine spray of water droplets inside the cylinder is acted on by the spark, and a secondary electrical supply from an inverter boosts the spark, forming a plasma discharge. The result is a power stroke nearly as powerful as using a fossil fuel. For the moment, let us also ignore that style of operation.

This document describes another system which uses water and air as the primary fuels, but again, does not use electrolysis to generate hydroxy gas for use in the engine. Instead, the objective is to create a continuous supply of Nitrogen Hydroxide (NHO_2) for use as the fuel. This system has worked well for a number of people but there has been considerable intimidation and most of these people are very reluctant to pass the information on. This document is an attempt to present those details clearly enough to allow the system to be replicated by anyone who wishes to do so.

So, how exactly is this fuel generated? The production method is described as the fuel gas being synthesised by a mixture of stream water and rock salt (the mineral "halite") in the presence of air, being acted on by engine "vacuum", electrolysis and a strong magnetic field. This fuel is said to be more powerful than hydrogen and is a much more viable fuel source as less of it is needed to run an internal combustion engine.

This system may be used with any internal combustion engine, whether used in a vehicle or stationary when powering an electrical generator or other equipment. The additional equipment consists of one, or more, horizontal cylinders mounted near the engine. A single, horizontally mounted, cylinder can generate sufficient gas to power an internal combustion engine up to two litres in capacity. Larger engines will need two cylinders to generate enough gas for them to operate.

It must be stressed that this is **not** a hydroxy gas electrolysis cell. One test vehicle has been run on this system for a distance of 3,000 miles (4,800 kilometers) and the liquid fuel used was only 2 litres of water and 2 gallons of petrol. Two litres of water converted to hydroxy gas will definitely not power a vehicle engine for anything like 3,000 miles, so let me stress again that the fuel being generated in this cell is Nitrogen Hydroxide (NHO_2). It should be noted that if the cell described here is used as a booster for the original fossil fuel, then it will not be necessary to upgrade the engine by fitting stainless steel valves, piston rings, exhaust system, etc.

The person using this system which is shown in the following photograph, has opted for an exceptionally long generation tube attached to his stationary generator:

The versions of this cell design shown in the previous photograph and the following photograph, are early models which were in use before it was discovered that there was a considerable enhancement in gas production if a coil is wrapped around the cylinder.

For vehicle operation, it is more normal to have a shorter cylinder, (or pair of cylinders if the engine capacity is large) as can be seen in the following photograph of a 4-litre, 8-cylinder vehicle engine which uses this system. Engines of up to 2 litre capacity can be powered by a single horizontal cell, while two cells are used for larger engines.

The construction details are not difficult to follow and the materials needed are not particularly difficult to find nor expensive to buy. The main body of the device is constructed as shown in the following diagram. A chamber is constructed from a piece of 316L Grade (food quality) stainless steel pipe, 300 mm (12 inches) long and 100 mm (4 inches) in diameter. The length of 300 mm is chosen for convenience of fitting in the engine compartment of a vehicle. If there is plenty of room there, the length can be extended for better gas performance and water capacity. If that is done, keep the 100 mm cylinder diameter and all of the clearance dimensions mentioned below.

The chamber is sealed at each end with 12 mm (half inch) thick discs made from "Lexan" (a very strong polycarbonate resin thermoplastic). These discs have a 3 mm (1/8") deep groove cut into their inner faces. The groove is there for the cylinder to fit into when the discs are clamped in place and held by stainless steel

nuts tightened on a 10 mm (3/8") stainless steel threaded rod. To combat engine vibration, a lock nut is used to clamp the retaining nuts in place. The threaded rod also provides the contact point for the negative side of the electrical supply and a stainless steel bolt is TIG welded to the outside of the cylinder to form the connection point for the positive side of the electrical supply.

This basic container is modified in a number of ways. Firstly, a small 3 mm (1/8 inch) diameter air intake pipe is provided in one of the Lexan discs. This air intake is provided with a needle-valve which is screwed tightly shut for the early stages of testing and only eased slightly open when the engine is actually running.

Also fitted is an 12 mm (1/2") stainless steel pipe, attached to the stainless steel cylinder to form a gas supply feed to the engine. A one-way valve is placed in this pipe as the design calls for the cylinder to be maintained at a pressure which is less than the outside atmosphere. The lower the pressure inside the cell, the greater the rate of gas production. The one-way valve allows flow into the engine but blocks any flow from the engine into the cylinder. This valve is the same type as is used in the vehicle's vacuum brake booster system.

The gas outlet pipe is continued from the one-way valve using plastic tubing for a few inches. This is to prevent an electrical connection between the stainless steel cylinder which is connected to the positive side of the electrical supply, and the engine manifold which is connected to the negative side of the electrical supply. If this pipe were metal all the way, then that would create a direct electrical short-circuit. The pipe running to the engine intake manifold needs to be made of metal in the area near the engine, due to the high engine temperature, so stainless steel pipe should be used for the last part of the gas supply pipe running to the engine. The gas supply pipe fitting is made to the most central of the bungs fitted to the manifold.

For the initial testing period, a filling port with a screw cap is mounted on the top of the cylinder, in order to allow the water inside to be topped up as necessary. Later on, if long journeys are made on a regular basis,

then it is worth fitting a separate water tank, water-level sensor and water injection system using a standard vehicle windscreen washer water pump. The topping up is done with water alone as the rock salt additive does not get used in the process and so does not need to be replaced. With these additional features, the gas generation cell looks like this:

There is one further step, and that is to add an inner cylinder of 316L grade stainless steel. This cylinder is 274 mm (10.75 inches) long and 80 mm (3.15") in diameter. Both cylinders have a wall thickness of 1 mm. The inner cylinder is supported on the central threaded bar and it is clamped in place with retaining nuts. A supporting lug is created by making two cuts at each end of the cylinder, drilling a hole and then bending the lug up inside the cylinder at right angles to its axis. This needs to be done accurately, otherwise the inner cylinder will not lie parallel to the threaded rod, or alternatively, not be centred on the threaded rod. The centre of the 10 mm (3/8") hole is positioned 8 mm (5/16") in from the end of the cylinder. Two 48 mm (1.9") long cuts are made each side of the hole, positioned to be about 5 mm (3/16") clear of the hole - this measurement is not critical. This is done at each end of the cylinder and the holes are positioned exactly opposite one another, along the axis of the cylinder, as shown here:

The inner cylinder is secured in position by two bolts as shown here:

The inner nuts are manoeuvred on inside on of the lugs by hand and then the threaded rod is rotated to move one nut to the inside of the other lug, while the nearer nut is held to prevent it rotating. When the rod is positioned correctly and the inner nuts are pressed up hard against the lugs, then a box spanner is used to lock the outer nuts tightly against the lugs, forming a strong mounting lock.

The inner cylinder is inserted inside the outer cylinder, the Lexan end discs are then added and the outer lock nuts added to produce this arrangement:

This gives a 9 mm clearance between the two cylinders and this gap stretches 360 degrees around the cylinders. The inner cylinder is located 10 mm clear of the Lexan end discs.

The units is completed by winding a coil of 2 mm diameter insulated copper wire tightly around the full length of the outer cylinder and filling the unit with electrolyte to a level of 3 mm (1/8 inch) above the top of the inner cylinder as shown here:

The wire used for the coil is heavy duty copper wire with an inner diameter of 2 mm, i.e. British 14 SWG wire or American 12 AWG wire. The coil is held in position at the ends of the cylinder, with plastic cable ties, as these are non-magnetic. This coil is of major importance in this design as the strong magnetic field produced by it has a very marked effect on the performance of the cell. The magnetic field produced by this coil, increases the gas production by anything from 30% to 50% and increases the production of Nitrogen Hydroxide by a factor of ten times. The electrical connection of the coil is in series with the cell, so the battery positive is not taken directly to the bolt welded to the outer cylinder, but instead it passes through the coil winding before being connected to the outer cylinder.

Installation and Use

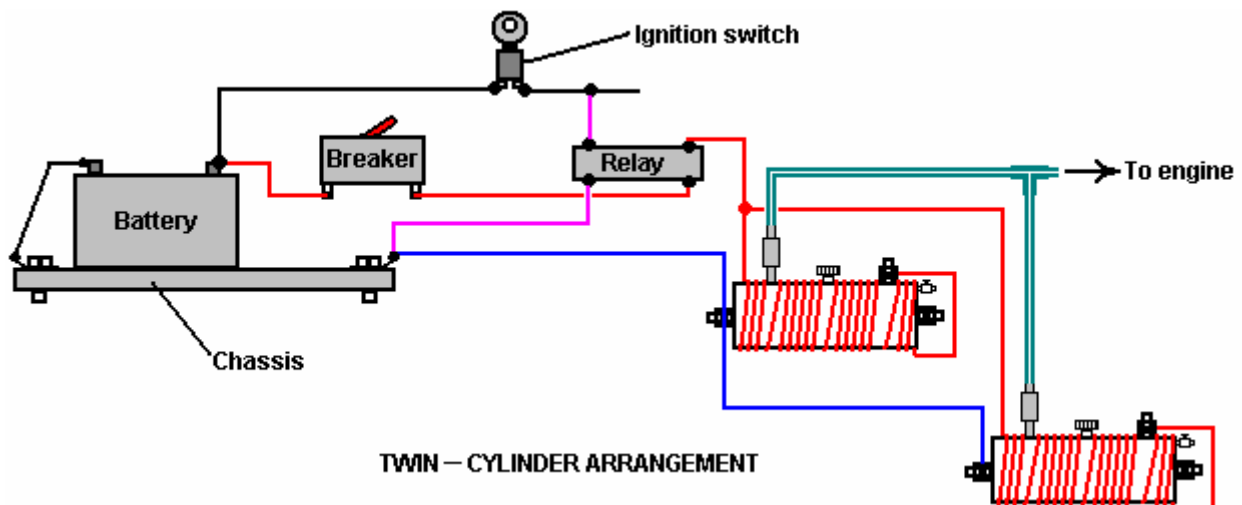

The gas outlet pipe is connected directly to a vacuum port directly below the carburettor on the manifold of the engine. This connection is important as the cell relies on the "vacuum" (actually reduced air pressure) produced by the engine intake stroke, as part of it's gas-forming process.

The exact method of mounting the cell in a vehicle depends on the vehicle, so this is something which you will need to think out for yourself. Be sure that you insulate the cell from the metal bodywork of the vehicle and I would suggest that you keep it away from the high-voltage electrical wiring (coil, distributor, spark plug leads, etc.).

The electrical connection arrangement is as shown here:

Or for larger engines:

The method of electrical connection is important. It is vital that the electrical supply is disconnected when the engine is not running. For that reason, the power to the cell(s) is taken via the vehicle's ignition switch. In order not to load that switch unduly, a standard automotive relay is used to carry the main current, leaving

just the relay current to be handled by the ignition switch. Also, a 30 amp circuit-breaker or fuse is placed in the circuit, immediately after the battery connection. In the unlikely event of some physical problem with the cell occurring, this device will disconnect the power instantly and avoid any possibility of a short-circuit causing a fire, or of excess gas being produced when it is not needed

The water to be used in this cell needs to be selected carefully. Tap water is not acceptable as it will be contaminated with several additives - fluorine, chlorine, etc. put in it when going through the purification process of the supply company and many other chemicals picked up along the way. It is considered very important that the water be taken from a stream, preferably from where it rises, as that is the point of greatest purity. May I also suggest that the water be transported in either glass containers or stainless steel containers as these help to maintain the purity. Avoid plastic containers, because while these appear to be completely inert, they frequently are most definitely not and chemicals from their manufacture can, and do, enter any liquid contained in them.

The cell is filled to a depth of 25 mm (1 inch) below the top of the outer cylinder and then (on the first occasion only) one or two grains of rock salt are added to the cell. This addition needs to be minimal as it controls the current draw from the electrical system and the strength of the magnetic field created by that current. After using the cell for at least a week, if the gas rate is not adequate, then add one more grain of rock salt.

Getting the cell attuned to the vehicle is likely to take at least a week of use. The cell is put in place and the vehicle run using its normal fuel. The needle valve on the cell's air intake is kept completely closed during this period. The inventor opted to continue running his engine on very small amounts of petrol plus this new gas fuel - the result being 3,000 miles covered on just two gallons of petrol. If you consider this as still being a petrol powered vehicle, then getting 1,500 mpg is quite an achievement - I certainly would settle for that.

When the cell is first connected, you will notice that the engine ticks over faster and tends to rev more than it did before. It will take several days for the system to settle down. Part of this is believed to be the effect of the new magnetic coil in the engine compartment. It may be that the metal parts of the vehicle have to take up a magnetic alignment which matches the magnetic field produced by the cell. Whether that is so or not, it will take a few days before the system settles down into its final state.

It should be realised that if the vehicle has a fuel-control computer with an oxygen sensor mounted in the exhaust stream, then the oxygen sensor signal will need to be adjusted. The D17.pdf document of this series, shows in detail how to do this, should it be necessary. If the vehicle has a carburettor, then there is an advantage in fitting a one inch bore carburettor of the type found on lawnmowers, as this promotes lower pressure inside the manifold and promotes good cell operation as the lower the pressure (or the greater the "vacuum"), the higher becomes the rate of gas production.

Practical Details

The original end pieces were cut and grooved using a lathe. Most people do not own or have access to a lathe so an alternative method of cutting the discs needs to be used. The essential part of this operation is to cut an accurate groove to take the 100 mm stainless steel outer cylinder. The groove needs to be cut accurately as it needs to form an airtight seal on the end of the cylinder. Consequently, the end of the cylinder and the bottom of the groove, both need to be straight and true if they are to mate securely.

An alternative method is to use an adjustable hole-cutter drill attachment. If this is used with a drill press or a vertical stand adaptor for an electric hand drill, then if care is taken, an accurate groove of the correct dimensions can be cut. As an extra precaution, a thin layer of marine grade white "SikaFlex 291" bedding compound can be used in the bottom of the groove. Two things here. Firstly, only use the genuine Sikaflex 291 compound even though it is far more expensive than other products which claim to be equivalents - they aren't, so pay for the genuine product. Secondly, we do not want the slightest trace of the Sikaflex contacting the electrolyte if we can avoid it, so be very sparing in the amount put into the groove, no matter what you paid for it. Make sure that the bedding compound is placed only in the very bottom of the groove and not on the sides. When the cylinder is forced into the groove, a very small amount of the compound will be driven into any gap between the cylinder and the sides of the groove.

What is needed is a result which looks like this:

The other important part of this joint is the end of the outer cylinder. It is recommended that the cylinder be cut by hand with a hacksaw to avoid generating excessive heat which can affect the structure of the metal. To get the end exactly square, use a piece of printer paper. This has straight edges and square corners, so wrap it flat around the cylinder and manoeuvre it into place so that the overlapping edges match exactly on both sides. If the paper is flat and tight against the cylinder and the edges match exactly, then the edge of the paper will be an exact true and square line around the cylinder. Mark along the edge of the paper with a felt pen and then use that line as a guide to a perfectly square cut. To avoid excessive heat, do not use any power tool like an angle grinder on the cylinder. Just clean the edges of the cut gently with a hand file.

In the diagrams shown earlier, the gas pipe, water-filler cap and the battery positive connection bolt have all been shown on the top of the cylinder. This is only to show them clearly, and there is no need to have them positioned like that. You will notice that they all get in the way of the wire coil, which is not an advantage.

It is necessary for the gas pipe to be positioned at the top as that gives the best clearance above the water surface. The clearance should be maintained at 25 mm (1 inch). The water-filler cap which was shown on top of the cylinder, would be better positioned on one of the end caps as that would keep it out of the way of the coil of wire:

This arrangement has the advantage that it does not require a filler hole to be drilled through the steel cylinder.

It is necessary for the electrical connection to be welded to the cylinder, but it is not necessary to have a head on the bolt as that just gets in the way of the electrical coil. The best strategy is to use a longer bolt of small diameter, remove the head and weld the shaft in place with spot welds which will not get in the way of the coil, as shown below. Spot welds are very quick to make, but even they generate a good deal of heat in the pipe. Some people prefer to silver-solder the bolt shaft to the cylinder as the heating is less.

The bolt is kept just clear of the end cap to avoid fouling it when it is clamped on to the cylinder. A lock nut is used to keep the solder tag assembly clear of the outer edge of the end cap. This allows the wire coil to be wound right up to the bolt. It does not matter which end of the coil is connected to the outer cylinder, but common sense suggests that the end nearest the bolt is connected to the bolt. It is, however, important that once connected, the electrical connections to the coil are maintained ever afterwards, to ensure that the magnetic field stays in the same direction. Remember that the surrounding metal parts of the vehicle will take up a magnetic orientation matching that of the coil's magnetic field, so you do not want to keep changing the direction of the coil's magnetic field.

When welding the bolt to the outer cylinder, be sure you use stainless steel wire. The joint needs to be made with a MIG or TIG welder. If you don't have one and can't hire one, then your local metal fabrication shop will make the spot welds for you in less than a minute and probably not charge you for doing them.

The grade of stainless steel in the cylinders is important. Grade 316L is nearly non-magnetic, so if you hold the cylinder with its sides vertical and place a magnet against the cylinder, the magnet should fall off under its own weight. Try this test no matter what grade the stainless steel is supposed to be, as some steels are not labelled correctly. There is a good chance that you will be able to find suitable tubing at your local scrap yard, but be careful on sizing. The 9 mm gap between the outer 100 mm diameter cylinder and the inner cylinder's 80 mm diameter, is very important indeed. This gap needs to be 9 mm (11/32 inch) so if really necessary to vary the diameters slightly up or down, be sure to pick material which gives the correct gap between the cylinders. Seamless piping is usually preferred to pipes which have seams as the seam welding tends to generate a magnetic effect in the steel. However, if a seamed pipe passes the magnet test with the magnet falling off it, it is definitely good material for the cell.

If you can get it, a good material for the 12 mm (1/2 inch) pipe running to the carburettor manifold, is aluminium. Please remember that the one-way valve on the cell's output pipe needs to be connected to this pipe with a material which insulates the two metal components. The suggested piping is therefore: the cell output is via a stainless steel pipe connector, connected directly to the one-way valve, which then has a plastic pipe connection to the aluminium tube which runs all the way to the manifold. Please remember to insulate the cell from the vehicle chassis and components to avoid a short-circuit.

An alternative to using the rather expensive "Lexan" for the end caps, is to use "UHMWP" - Ultra-High Molecular Weight Polyethylene which is cheap and easy to obtain as plastic food-chopping boards are usually made from it. The advantage of Lexan is that it is transparent and so the level of the electrolyte can be seen without the need for removing the water-filler cap.

It has been suggested that the topping up of water in the cell can be automatic if you wish it to be so. For this, a water-level sensor circuit is used to drive a standard windscreen-washer water pump when the level of the electrolyte falls below the design level. The sensor itself, can be a bolt running through one of the end caps as shown here:

When the electrolyte level drops below the upper bolt, the circuit contact to the control circuit is broken and the circuit responds by powering up the water pump, which injects a little water to bring the electrolyte level back up to where it should be. When the vehicle is moving, the surface of the electrolyte will not be steady as shown in the diagram, so the control circuit needs to have an averaging section which prevents the water pump being switched on until the circuit input has been missing for several seconds.

Circuitry suitable for this is shown in Chapter 12, and there is no reason why you should not design and build your own circuit for this.

In the initial stages of testing and installation, when adding rock salt, be very sparing indeed. Add just one grain at a time because the salt ions are very effective in carrying current through the electrolyte solution. Also, if too much is added, it is difficult to reduce the concentration as more water needs to be added, which involves draining off some of the water already in the cell. It is much easier to take your time and add very, very little salt. Give the salt grain plenty of time to dissolve and spread out throughout the electrolyte before checking the cell performance again.

Let me remind you that during the initial cell testing, the air intake needle valve is closed completely and it is not eased open until the engine is running satisfactorily. In the engine acclimatisation period, the engine should be run on it's normal fuel and the cell just used as a booster. Remember that it will take at least a week for the vehicle to settle down to it's new method of operation. There is no particular hurry, so take your time and don't rush things.

If the vehicle is fitted with computer control of the fuel supply, it may be necessary to apply some control to the unit by adjusting the signal coming from the oxygen sensor placed in the vehicle's exhaust system. The information on how to do this is shown in considerable detail in Chapter 10.

Some questions have been asked about this cell:

1. Does petrol have to be used or can the engine be run on the cell alone?

Answer: No, you can eventually eliminate petrol altogether but the engine runs so cleanly that old carbon deposits around the piston rings and elsewhere will get cleaned away and the components may rust. These parts can eventually be replaced with stainless steel versions or instead of that, it is probably possible to avoid replacements by the use of the oil additive called "Vacclaisocryptene QX and Molybdenum Disulfide" - see <http://www.clickspokane.com/vacclaisocryptene/> for details. This additive reduces wear to such a degree that engine life may be doubled, no matter what fuel is being used.

2. Why is the unit 300 mm long?

Answer: Just for convenience in fitting it into the engine compartment. It can easily be longer if space allows it. The longer the unit, the greater the gas production and that is why two 300 mm cells are needed for engines over 2 litres in capacity.

3. Does the cell body need to be made from seamless pipe?

Answer: Seamless 316L-grade stainless steel is preferred.

4. How do you determine the amount of rock salt to add to the water in the cell?

Answer: The amount varies with the type and size of engine being dealt with. You want the minimum current through the coil so start with one grain and increase it only very gradually with tiny amounts. If the cell is being mounted in the engine compartment of a vehicle, then the make, model and size of the vehicle will affect the amount due to the magnetic effect of metal components near the cell.

5. Does it matter which end of the coil is attached to the outer cylinder?

Answer: No, it can be either end.

6. Is the pipe diameter shown from the cell to the engine the best size?

Answer: The 1/2 inch diameter is very good as it increases the "vacuum" inside the cell as the engine runs. When first testing the engine, remember that the needle valve is completely shut off, and when it is opened during tuning, it is only opened to a minimal setting.

7. Are the exhaust emissions damaging to the environment?

Answer: Some years ago, a Mercedes car dealer ran his own emissions test on a new Mercedes diesel, using his own equipment. He found that the emissions were reduced by 50% and the engine power increased by 12%. The engine ran better, cleaner and quieter. He was fired for doing this.

Other independent gas-analyser tests showed that there is an increase in water emissions and a drop in carbon emissions as less fossil fuel is used. It was also noted that the volume of gas produced by the cell was affected by where it was mounted in the engine compartment. This is thought to be due to the magnetic effect on the cell.

Update Information:

Question 1: Where do we connect the outlet hose from the D18 fuel system to the engine on a late model car with fuel injection system?

Response: There is a throttle body on the engine and it is connected to a rubber hose which goes to the air filter. Typically, the rubber hose attaches to the throttle body and is clamped in place. A hole needs to be punched through the rubber housing approximately two inches (50 mm) from the throttle body. A brass fitting needs to be put into this opening. It will have a flange on one end and the other end will be threaded to accept a nut to hold it in place. This brass fitting will be the attachment point for the incoming fuel line from the D18 system and/or any other booster. For the D18 horizontal system, the size of the fitting should be half-inch (12 mm) so as to be able to maintain the proper vacuum pressure to the D18 fuel system.

Important Note: Since the practice of using alternate fuels by the public is not widely accepted it would be expedient to locate the fuel inlet opening on the under side of the hose out of plain view. This will help the user pass vehicle inspections and keep inquisitive persons from asking too many questions.

Question 2: What do I have to do to make the on-board computer function properly with my new booster?

Response: You need to install an electronic mixer control system. Plans for such a system used to be downloaded from <http://www.better-mileage.com>. This control system will fool the on-board ECU into thinking that all is okay and it will continue to work as normal with no problems. There are two corrections that need to be made to the system to make it work properly. They are outlined in red on this diagram:

Note: In this application the D18 cell is only being used as a booster. Therefore the engine still is using a hydrocarbon fuel. There are numerous systems available such as “megasquirt”, which allow for tweaking the amount of fuel being injected into the engine, and for making numerous other on-board computer adjustments to your Electronic Control Unit, for those of you who want to use nitrogen hydroxide as your only fuel and/or want to reduce the amount of petrol being injected into the engine.

Air Inlet Port: None required!

Ageing of Cell / Cell Break In: Use only the proper water as described below. The cell needs to be drained every day during the ageing process. Filter the water five to seven times through a cotton T-shirt. Collect the water only in glass jars, and do not touch it with your bare hands. Re-use the water and top the cell up with the proper water. Use absolutely no electrolytes (such as salt or potassium hydroxide). You can use natural water which has not seen light and that has not been charged such as, well, cave, or spring water at it's source. Age the cell until it becomes a slight bronze in colour and does not generate any more gunk inside the cell. The purpose of the break-in period is to purge impurities from the cell.

Cell Current: The peak electrical current with the proper water is approximately 10 amps.

The Positive Electrode: the inner cylinder should be connected to the battery positive. This should be done via an automotive relay to assure proper shutdown of the cell when the engine has been switched off.

The Negative Electrode: This is the outer cylinder, which is connected via a metal strap to the chassis.

Construction: The inner cylinder is separated from the outer cylinder by spacers made out of ebonite or any other material which will not deteriorate within the cell. The objective is to keep the plates at an equal 9 mm spacing throughout the cell. The inner cylinder is connected to the threaded rod via a stainless steel wire strap, which is silver soldered in place at both ends of the cylinder. The threaded rod forms the battery positive connection point on the outside of the cell.

Drain: There should be a drain at the bottom of one of the end plates, so that you can drain the cell without having to remove it from the vehicle. The water will need to be drained and filtered at least once every three weeks. Drain the cell contents into a glass container. Do not touch the water with your bare hands. Filter the water at least five times (seven is better). Use a cotton T-shirt for filtering. Never throw the water away but just filter it. Put the water back in the cell and top the cell off using only pre-charged water.

Electrical Generation: The cell will continue to produce electricity after engine shutdown which will also lead to gas production, so take the precaution of discharging the cell.

Electrolyte: Use absolutely no electrolyte (including salt) at any time. This has been found to decrease the fuel output of the cell and also to have caused unnecessary damage to the plates of the cell.

Engine Timing: Yes, you have to adjust it to your engine. This is a very important aspect of getting high mileage with this system. Each engine is different and therefore each engine has a different adjustment.

Fuel Outlet Piping: Copper piping is recommended as unlike plastic or rubber, it will reduce condensation of water into the fuel lines and thereby reduce the level of water getting into the engine.

Fuel Outlet Ports: There are two of them positioned on opposing ends of the cell. If you are using a 12" cell, then they are positioned 3" in from each end of the cell. If you are using an 8" cell then they are positioned 2" in from each end of the cell. Make one outlet port half-inch (12 mm) in diameter and the other three-quarter of an inch (18 mm) in diameter. Make sure that the piping from the ports extends into the cell by at least an eighth of an inch (3 mm). This is to prevent water vapour accumulating at the top of the cell from entering the fuel outlet ports. This measure has been found to reduce water reaching the engine.

Leak Prevention: Use rubber gaskets - these can be the type used for domestic plumbing.

One-way Valves: One-way valves are not used on the fuel outlet pipes.

Outlet Pipe Connections: The half-inch (12 mm) pipe is connected to the engine after the butterfly valve, while the three-quarters of an inch (18 mm) pipe is connected to the engine before the butterfly valve.

Cylinder Preparation: The inside of the 4" (100 mm) outer cylinder and the outside of the inner cylinder, which are the opposing cell plates should be sanded very well with medium grit sand paper to rough up the surface. Two sanding directions at right angles to each other should be used. This will insure better cell productivity later. It is important that there should be no direct contact between the cell plates and your bare hands, so wear rubber gloves when sanding and then assembling the cell.

Voltage: Only 12 volts is required to run the cell, a typical car battery is all you need to power the cell.

Water Selection: Use only natural water that has come out of the ground and not seen light such as well, cave, or spring water at it's source. **Important:** Only add charged water to the cell. Water being used must have a pH of somewhere between 6.4 & 6.5 (slightly acidic). Do not use water with a pH of 7 or higher. The water is charged using a regular Joe Cell with electrodes separated by 3/16" (5 mm) for best results. The details of a Joe Cell can be found in D10.pdf which is a document in this series.

Water Level: Maintain the water level at approximately half full, that is, just covering the threaded rod.

E-mail from a contact:

Hi,

Thanks so much for shedding light into my cell cleaning concerns. I haven't been posting lately since right now the cell is already hooked up in my test car and I've been doing some tests with it day and night.

For once, I can personally tell you that the cell in fact works! However, with my results, it is hard to believe that the Nitrogen Hydroxide produced is enough to make the car get 1500 mpg. When the Nitrogen Hydroxide is allowed to enter the engine, the car starts to rev erratically for 2-3 minutes and then steadies itself thereafter. I noticed an increase of about 800-1400 rpm in my ECU data-logger once the Nitrogen Hydroxide cell is put into the equation. I then adjusted my Engine Management System and removed 15% of the petrol going into the system and drove around the block for a good 15 minutes or so. My exhaust gas temperature rose from 90 Celsius to 97 Celsius which is still fairly acceptable.

I went back to the garage and further adjusted the petrol to less 20% in total and at this point, the car began to vibrate erratically as if it was gasping for air. Upon noticing this, I concluded that not enough NOH must be getting into the ICE or something. The next thing I did was I mounted my old 304L cell alongside with the 316L currently installed. With two cells in the equation, petrol at 20% less did not cause vibrations at all, but mind you that even at 50% less petrol and without Nitrogen Hydroxide cells installed, the car will still run by petrol alone. It was getting dark and so I maxed out my engine management and removed 50% petrol from

the equation with the two NOH cells running side by side. Again, there were vibrations and it was very evident but my brother and I drove the car around the block anyway. Within just five minutes of leaving the garage, the engine temperature rose from 97 Celsius to 111 Celsius and was still rising. I also noticed that the car was underpowered to say the least. We drove up and down a parking complex to test out the non-sloshing design and from my guess it performed pretty well.

To cut a long story short, the cell produced some kind of fuel (NOH or HHO), but it was not enough to power the car when 50% petrol was removed even with 2 cells running. I am currently getting 22 mpg with this test car so I assume that 50% less petrol should give me something like 44 mpg on city driving and probably 60 mpg for long trips. These numbers are very small as compared to the 1500 mpg that the inventor reported. Maybe the cell needs more time to acclimatise to the test car... but I've been getting same results for 3 days now.

I am currently building two new 316L cells which will incorporate my non-slosh design and which have a vacuum-powered water top up system. I also believe that the gap inside the 3" cell should be sealed off since there is no reaction happening in this part of the cell and it only increases the resistance of the water to electricity. I also included this in my new cell design. I will probably publish it if I find that it produces more gas than the D18 design.

By the way, I've contacted someone in my city who sells 914L stainless steel. However, he told me that 914L requires special handling and special tools and it is much much harder to work on with hand tools alone. He gave me a 1" diameter tube as a sample to see if I can work with it. It's really, really expensive. One cut of a 4" diameter 914L will cost just as much as 2 years worth of gasoline (around 70 FULL TANKS).

And: Bore water is water pump out of the ground. It is similar to well water, the only difference being in the way the water is gathered. Well water is dug from the ground while bore water is SUCKED out of the ground by means of an electric or manual pump.

What I noticed so far is that there is really a lot of steaming going on inside the cell. Converting steam into Hydroxy Gas requires less power than water, so I suspect that this steaming is good. The suggestion to only fill the cylinder half-way actually makes sense as this would allow a greater storage space for the steam and pretty much eliminates water sloshing problems. I have also tried switching the polarities on my 304L cell a couple of times but it did not make any noticeable difference. I will try to make a test run with a half-filled cell and tell you my results.

And: The outlet tubes are positioned at 3" on both ends as this might be the optimum position where less water will accidentally splash into the ports. I was also told that these tubes extend inwards into the cell for about 3 mm so that the water building up in the top surface will not be allowed to slide accidentally into the outlet tubes. It makes sense because with the tubes positioned at 3" away from the edge, it actually gives you about 30 degrees of angle before one of the ports are completely submerged in the water. Also, if the cell is just half-filled, this could actually give us 45 degrees which is relatively a very steep slope to say the least.

The 1/2" and the 3/4" remains a mystery for me. The only reason I can think of is that one of these tubes might be directed before the butterfly valve and the other one placed after the butterfly valve. I would suspect that the smaller tube (1/2") was placed after the butterfly valve and the larger tube was placed before the butterfly valve. This will make sense because the negative pressure during idle is naturally constant would only require less NOH, while stepping on the accelerator will result in variable pressures which will require larger amounts of NOH. This is only my theory and I am in no position to declare that this is in fact the reason behind the different tube sizes.

I cannot measure the amount of air entering my cell because my end caps are not see-through plexiglass. I only open my Air Inlet Valve halfway through. At this position, I could see a difference in the rpm and at the same time no water could be seen creeping into the tubes. If I open the valve all the way, the rpm will continue to increase but at the same time so does the water in the tubes.

This is my third installation and probably the most successful one. It has been on my test car for five days now but it was not switched on all the time. I found too much water creeping in into the tubes and so I had to shut it off and run the car normally just to make sure no rusting will occur in my engine. I estimate that I have the cell switched on and running for a total of maybe 12 to 14 hours as of today.

From another user:

Hi,

thanks for the info about the EFI thing! it worked on my wife's Passat. After a few weeks of searching we were able to find smaller injectors for the car as the variable resistor trick only gave us CEL errors. I do notice that the engine's rpm is changing somewhat with every turn of the variable resistor but the relationship is far from linear.

The cell will in fact continue to produce fuel for some time after the power source has been cut. This will tell you that you have the correct water in your cell and you should be happy! What you should do, is to mount a small 12V computer fan beside your cell so that this fan will feed on the power created by cell and reduce the fuel build-up. If you want to be totally safe, then you should put another outlet port on top of the cell and open this every time you park your vehicle. If you want to automate things to avoid constant accessing of the cell, then you can get an electronic valve which will also feed on the excess power produced by the cell. I will not explain further on how this can be achieved, but basically, the valve and fan should only be activated when the engine is off. A few switches here and there will do the trick.

Regarding outlet ports, you are correct to assume that you should have separate lines. One line before the butterfly valve and another line after it, is quite correct and this is what I am doing right now. You should however, have the means to regulate these lines as you will soon realise that too much fuel is actually bad for the engine's health. Also make sure to top up the water regularly as too much empty space inside the cell will make the cell into a bomb!

My concern right now is that if our cells were made half-filled, then it would mean that more than a litre of empty space would be left inside the cell. One litre of Hydroxy or Nitrogen Hydroxide will definitely turn our D18s into a bomb. We should therefore provide a means of venting the NOH build-up when the car is parked. My cell does not produce 13v when shut off as of this moment, which obviously explains the inefficiency I am getting.

Another person:

Hi,

I've seen your set-up pictures at photobucket and I am surprised at the level of professionalism that you are dedicating into this project. I am even more surprised that you claim that your current set-up doesn't work at all! What gives???

Now for my take on your set-up: it seems that the pipes you are using are too small... is it 1/4" ? If so, try to use 1/2" as the minimum. Your fuel output on the end caps should be placed on top of the cell, as I previously stated in my messages. Your water inlet valve should be placed lower. I think the main problem of your set-up is that the introduction of air is placed very near your fuel output. Try to keep these two as far away from each other as possible.

Do not rely on the inventor's set-up as shown on the famous picture on his V8. This picture circulated years ago and to my knowledge, this is not the current set-up that gave him extreme mileage. Last I heard about this guy was that he also used a petrol vaporiser and this was one of the key components in achieving unimaginable mileage on his truck. I for one am not getting even half the mileage that this guy claims. With years of tweaking an old carby truck, I was able to get 225 mpg and this was good enough for me because sometimes I get 300+ on long drives to the country. You should also bear in mind that the longer that petrol stays in your tank, the more evaporation will take place. Upon installing a high mileage device, I realised that most of the petrol is wasted by just sitting in the tank and evaporating.

The air inlet port should be kept as far away from the output ports as possible. It is the water that does the work and not the stainless steel. It should be possible to drain the water completely without removing the cell from the car. The air inlet is a dual purpose port which is placed on the dead bottom of the end caps. Tuning the car to work efficiently with the cell can take a very long time. Make sure that the cell is producing gas aggressively before mounting it on the car.

If you always have the fuel tank full at all times, it reduces fuel loss through evaporation, since on a hot summer day, you are probably losing 12-18% of the fuel through evaporation and what will be left inside the

tank will be less volatile, with bigger molecule sizes which won't combust completely in the engine, which in turn, shortens the life of the catalytic converter and causes more pollution.

System Summary by Contact: I use two 8" cells on my truck with two gas ports on each cell for a total of four ports. Two Ports to Manifold and two Ports to air intake, and there are no one-way valves, instead I use small fuel filters to make sure that water entering the engine is minimised, and at the same time oil is prevented from going into the cell.

I drilled a small hole on the bottom of both fuel filters and sealed them with a small screw plus a rubber ring. From time to time, I remove the screw to drain the water from the filters. The water inside the filters is dirty and should not be recycled for use in the cell. No salt or KOH is used because once the cell is aged and ready, catalysts are no longer required as they will only produce more dirt inside the cells.

Now here comes the most controversial part... NO AIR INLET PORT OPENING!! I don't have an opening for air in my cells. I'm sorry that I've been keeping this from you since day one. I know I told you about properly proportioning your air to the amount of gas that your cell produces. This was the same information that I got from another guy years ago. Although this might be true, you can never be precise on how much gas your cell is producing as the temperatures and pressures you get in the engine vary from time to time... Right now you might be thinking that I may be using a different system all along... this is what I was wanting to avoid that is why I withheld this information from you. But don't worry, there's an explanation for everything...

Simple analysis of the cell design will tell you that it is plainly impossible to remove all the air inside the cell. Air will always enter the weakest point in your cell no matter how air-tight you think your cell is. Take your tires for example: air is continuously escaping your tires no matter how air-tight you may think they are. Needless to say, your cell is not air-tight to begin with so why the hell would you need another air opening? As controversial as I may sound, I found this design to be the most efficient.

I use a Joe Cell to charge/clean my water. I don't have a working Joe Cell, I just use it for electrolysis to remove the junk out of the water before putting it in the cells in my car. I have a drain valve on the bottom of one cap and I usually drain and filter my cell water whenever I feel like it. If you have good water and an aged cell, you will produce hydroxy in no time. 304, 316, 317 stainless steel - it does not matter, just as long as you are able to produce gas and that it does not rust quickly. More expensive s/s will tend to outperform cheaper s/s but cheap s/s will still work!

I don't have a magnetic coil and I never heard of this until you pointed it out to me. It did not take me weeks to age the cell, the hard part is really the water. You can use plain old tap and maybe get some gas... hooray! You have just made a hydrogen booster! Or you can follow my lead, and use good water and make fossil fuel nearly obsolete. The water level inside the cell may not matter, but I find that the cell will produce more gas when there is less water inside it. However, for safety reasons, I almost always make sure that the cell is 3/4 filled with water and 1/4 empty space. Another important thing to bear in mind is the steaming inside the cell. If you use plastic or rubber tubes, the steam might condense back into water before getting into the engine. Use copper tubes to make sure that steam will not condense. To my knowledge, the salt is just used to remove the protective layer on the s/s which actually prevents the bubbles from dislodging quickly. You can also age your cells in many other ways and this won't be a problem.

That main idea is, get your cells to produce hydroxy without using catalysts. The nitrogen part will come as an accident and I cannot explain how this happens. I am still a little sceptical about the nitrogen actually bonding with the hydroxide. Sometimes I think that it is only the hydroxy and steam which are doing all the work... You are entitled to your own opinion.

The wife gets around twice her previous mileage on the Passat. The injector change can only do so much. I only installed one 10" cell to keep all the stock parts intact. She is happy with it and so my EFI project stops here.

Please let me stress again that many people have built this device and tried to get it to work without any success whatsoever, and that is why it is in this chapter.

However, having emphasised those concerns and provisos, I was informed early in 2010, that Jim Bundock in the UK has had considerable success using this design as a booster. He estimates that using this device has saved him about £500 over a two year period. Here is some detail from him:

These two cells have been in use in two different vehicles for more than a year now. The vehicles are Ford Transit vans with 2.5 litre diesel engines. One is sixteen years old and the other is seventeen years old and the Nitro Cells have given a 10 mpg improvement from the day that they were installed in spite of the vans being heavily loaded when being used. The original mpg was 25, so the resulting 35 mpg represents a 40% improvement over a long period.

Jim says: these cells were built from the plans shown above, the only variation being that instead of bending the tabs for the inner tube, tabs were silver-soldered at the end of the inner tubes as shown here:

These cells are run without salt and they work equally well without the wire wrap suggested in the design. The vertical cell is 18 inches tall and 4 inches in diameter and it has a rubber diaphragm on top which acts both as a seal and as an anti-slosh device. The inner cylinder gives a 9 mm gap between the inner and outer cylinders. The cell ends and spacers are made from plastic food-chopping board. The top spacers are about 30 mm long as it was found that vibration tended to dislodge shorter ones. This vertical "slow" cell is very easy to build.

On one of the “fast” horizontal units, there is a length of blue pipe:

This prevents water from entering the engine when a certain boy-racer tries to negotiate corners at the speed of light. The horizontal cell was plumbed in using a plastic 12mm pipe connected to the inlet manifold. Personally, I don't think these cells like speed and they seem to respond best when driving around 50 mph – this is for a single cell on a diesel engine. The cell is wired in as standard, only on a diesel, the relay is connected to the fuel cut-off valve, making it very easy to wire, and when the engine is switched off, then the cell is turned off at the same time. Using a miniature version of the upright cell, the bore-hole water which I use, is pre-charged on the bench for as long as I feel it needs to be, just to remove some of the material suspended in it. Topping up with water is done every 750 miles or so and takes about an egg cup full of water. All in all, the Nitro Cell is a good honest working device, it is a simple drive-and-go piece of kit that has saved me around £500 in two years and will carry on doing that for ever.

The “HydroStar” and “HydroGen” Systems.

There are various sets of plans for car conversions and many of them are worthless and intended to waste the time and money of people who are interested in moving away from fossil fuel products. It is not possible for anyone to say with assurance that these plans do not work since even if you construct in exact accordance with the plans and your replication fails to come anywhere close to working, all that can be truthfully said is that your own replication was useless. We need to avoid this sort of comment, since for example, the Joe Cell does indeed work and can power a vehicle in a completely fuel-less mode, **but**, most people fail to get it operational. Consequently, it is completely wrong to write off the Joe Cell, but warnings on the difficulty of getting it working should always be given.

In the case of the HydroStar and HydroGen plans, I have never heard of anyone who has ever got either of them working. Also, experienced people are quite convinced that the design is seriously flawed and never worked in the first place. Still, it is up to you to make up your own mind on this, and so these plans are mentioned in this chapter.

The plans shown here can be downloaded free from <http://www.free-energy-info.tuks.nl/P62.pdf> and they are intended for free use by anyone who wants to use them. Please remember that should you decide to undertake any work of this nature, nobody other than yourself is in any way responsible for any loss or damage which might result. The full manual for an essentially updated version of the design is included under the name “HydroGen” and can be downloaded free from <http://www.free-energy-info.tuks.nl/P61.pdf>.

It is recommended that should experimental work be undertaken on a car, then the car chosen should be of little value and that all existing parts be kept so that the vehicle can be restored to its present fossil-oil

burning status should you choose to do so. It is also suggested that you use a car which is not important to your present transport needs. It is claimed that the modified car will travel 50 to 300 miles per gallon of water depending on how well it is tuned. The system is set up like this:

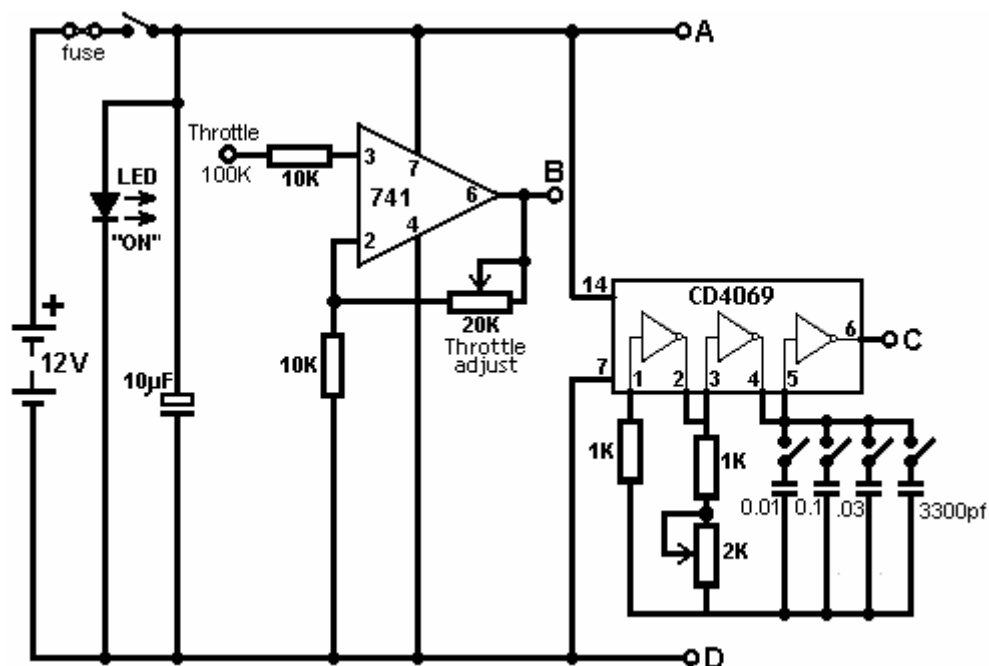

Here, the car has an extra tank installed to contain a reserve of water. This is used to maintain the water level in the reaction chamber which contains the electrode plates. The electrodes are driven by the electronics which applies a pulsed waveform to them in the 0.5 to 5.0 Amp range. The electronics box is powered directly from the existing car electrics. The Hydrogen/Oxygen mix which is the output from the reaction chamber is fed directly into the existing carburettor or fuel-injection system.

The start-up procedure is to power up the electronics and wait for the gas pressure to reach the 30 - 60 psi range. Then the car ignition is operated as normal to start the engine. The accelerator pedal is wired into the electronics to give more power to the electrode plates the further the pedal is pressed. This increases the gas production rate as the throttle is operated.

Electronic Control Circuit

The diagrams show a simple circuit to control and drive this mini-system. You are going to make a 'square-pulse' signal that you can watch on an oscilloscope. The premise given by the literature is: the faster you want to go down the road, the 'fatter' you make the pulses going into the reaction chamber. Duty cycle will vary with the throttle from a 10% Mark/Space ratio (10% on and 90% off) with the pedal up, to a 90% Mark/Space ratio with the pedal fully down.

There are many ways to generate pulses. This circuit uses an "NE555" integrated circuit. The output switching transistor must be rated at 5 Amps, 12V for pulsed operation.

The output of the 741 integrated circuit is adjusted via its 2K variable resistor, to give an output voltage (at point 'B' in the circuit diagram) of 1 Volt when the car throttle is fully up, and 4 Volts when the throttle is fully down.

The CD4069 is just an IC containing six inverters. It can handle a supply voltage of up to 18V and is wired here as an oscillator. Its four capacitors are likely to be used in just four combinations: C1, C+C2, C+C2+C3, and C1+C2+C3+C4 as these are the most widely spaced tuning ranges. There are, of course, eleven other capacitor combinations which can be switched with this arrangement of four switches.

Important Note

Gary of G. L. Chemelec commenting on "The HydroStar" circuit which sounds to be based on the same style of circuitry, states that the circuit and design are riddled with serious errors, some of which are:

1. The use of the 741 WILL NOT WORK! Pin 5 is a Voltage Control pin that already has its own voltage of 2/3 of the Supply voltage so it requires a pull down resistor, not an IC to control it.
2. The 2K Pulse width adjust will blow the 555 timer if adjusted all the way down. It needs an additional resistor to limit current to those pins on the IC.
3. The output of the 555, Pin 3 is fed to the CD4059 as well as a TC4420CPA (Mosfet Driver). This driver is a waste of money as it is not needed.
4. The Output of the TC4420CPA is then fed to the IFR510 Mosfet which is now obsolete, however you can use an RFP50N06 (50V, 60A).
5. There is no schematic of the CD4059. They should have shown pin 1 as in, pin 23 as out, pins 3, 10, 13, 14, and 24 connected to 12 volts and pins 2, 4, 5, 6, 7, 8, 9, 11, 12, 15, 16, 17, 18, 19, 20, 21, and 22 connected to ground.
6. The "Strength Adjust" Only Needs the variable resistor connected to Pin 5 and the Ground. The Connection of this control to the Supply Voltage Make Absolutely No Difference in the Output Waveforms, as the IC only needs a 2/3's voltage on this Pin and this is supplied internally, Within the IC.
7. The "Frequency Adjust", Connects to Pins 6 & 7 of This 555. Supply to the battery Will Destroy the 555. so another resistor is needed to prevent this from happening.

This is just a small list of what is wrong. There is MUCH MORE and even after the thing is built it does NOT WORK! If you want to experiment then please do, but I would suggest you just make your own Pulse Width Modulator.

There are also many problems with the design of the reaction chamber and simply put, even if you did get it to work you would need more of these units than you could ever fit in your car to even think about running the engine. Simply put, the unit will NOT create enough gas to run much of anything. Don't get me wrong, I do think that the idea is GREAT and that it can be done.

Reaction chamber:

The suggested reaction chamber arrangement is:

It is suggested that you use a section of 4" PVC waste pipe with a threaded screw-cap fitting on one end and a standard end-cap at the other. Make sure to drill-and-epoxy or tap threads through the PVC components for all fittings. Set and control the water level in the chamber so that the pipe electrodes are well covered and there is still ample headroom left to build up the hydrogen/oxygen gas pressure. Use stainless steel wires inside the chamber or otherwise use a protective coating; use insulated wires outside. Ensure that the epoxy seals are perfect or alternatively, lay down a bead of water-proof silicone sufficient to hold the pressure.

The screw fitting may require soft silicone sealant, or a gasket. Its purpose is to maintain the pressure in the cylinder and yet allow periodic inspection of the electrodes. Make sure that there are no leaks and you will have no problems. Make sure you get a symmetric 1.5 mm gap between the 2 stainless steel pipes. The referenced literature suggests that the closer to 1 mm you get, the better. Check that the chamber water-level sensor is working correctly before you epoxy its cap in place. Make your solder connections at the wire/electrode junctions nice, smooth, and solid; then apply a waterproof coating, e.g. the epoxy you use for joining the pipes to the screw cap. This epoxy must be waterproof and be capable of holding metal to plastic under pressure.

The suggested circuit for the reaction chamber water-level pump control is:

Hydrogen from Aluminium.

Since 2003 Rothman Technologies of Canada have been running a 12 HP petrol motor on hydrogen produced by a chemical process. This is a cheap process in which metal is consumed and so, although of great interest, this is not a 'free-energy' engine. A recent patent application by William Brinkley proposes a system where aluminium pipes are consumed by a 25% solution of Potassium Hydroxide heated to 180 degrees Fahrenheit. William remarks on the non-polluting nature of the system, but this is not really so in that a very large amount of energy has to be put into producing the aluminium metal in the smelting and refining process, and the pollution is just moved from the end user to the industrial plant, and much more importantly, the aluminium oxide produced is said to be highly toxic and cause a wide range of serious illnesses including Alzheimer's, although I have seen this disputed. Francis Cornish of the UK has a system where electrolysis of water is combined with a chemical process consuming aluminium wire. The system works well, but I have reservations about using consumables which tie you to industrial manufacturing, also concerns about the reliability of mechanical feed systems when they are being used by non-technical people (most car drivers). There is also the issue of removing and recycling the chemical residue generated by the process.

I personally am not keen on chemical processes and I do NOT recommend that you construct anything based on the following description. However, it might be possible to adapt the Brinkley system so that it operates with no moving parts:

Here, there is a header tank containing a 25% mixture of Potassium Hydroxide (KOH) in water. This tank is positioned higher than the pressure tank where the hydrogen gas is generated and the venting pipe is protected by a baffle. The venting pipe should provide an outlet to the air outside the vehicle or building which contains the system.

Initially, the KOH solution in the pressure tank is heated by the heating element, but when the process gets started, it generates heat to maintain the chemical reaction. The gas generation then builds up pressure in the strongly-built pressure tank. The raised pressure pushes some of the KOH solution back into the header tank, against gravity. This reduces the area of aluminium exposed to the KOH solution and reduces the rate of gas production. This effectively creates an automated gas production rate control which has no moving parts.

If the rate of gas taken by the engine increases, that lowers the pressure in the pressure tank, allowing more KOH solution to run into the pressure tank, increasing the rate of gas production. When the engine is stopped completely, then the KOH solution gets pushed into the header tank until all gas production stops, as shown here:

This looks as if the pressure tank is under considerable pressure, but that is not so, as the header tank is open to atmospheric pressure. I have concerns about controlling purely chemical processes rapidly enough for practical use. The above system would be more suited to a fixed engine, such as an electrical generator, where the gas requirement does not fluctuate greatly. The KOH tank shown above should be large enough to contain all of the KOH solution in case the gas production just does not stop when it should. The vent from the header tank should be capable of venting excess hydrogen with no possibility of it ponding on a ceiling and forming an explosive mixture with air. As far as I am aware, the above system has never been constructed and it is just shown here for discussion purposes.

Only 5 pounds per square inch of pressure is needed for electrolyser systems to feed a car engine satisfactorily, so a relatively low pressure is quite satisfactory, provided that the piping is of reasonable internal diameter. It should be remembered that the car engine will be applying a slight vacuum through the bubbler. As with all of these systems, it is vital that at least one bubbler is used between the gas production and the engine, to guard against flashback from the engine ignition if faulty ignition should occur. All bubblers should have a tightly fitting pop-off cap which can ease the effect of an explosion, and they should contain only a small amount of gas. The method of connection to the engine and the necessary timing adjustments are shown and explained in Chapter 10.

Francois Cornish Hydrogen System.

The method of using aluminium for a fuel in an on-demand hydrogen system for vehicle propulsion has been presented in detail by several people. One of the best known is the 1987 US Patent 4,702,894 by Francois Cornish, where he uses a feed mechanism for aluminium wire to maintain an underwater electrical arc which raises the water temperature high enough to make the aluminium react with the water. The rotating drum is made of aluminium but as it has a much larger thermal capacity than the aluminium wire being fed towards it, the drum temperature is much lower than that of the wire. As a result of this, the wire reaches the temperature required to make the aluminium react with the water. The chemical reaction releases hydrogen and converts the aluminium wire to aluminium oxide powder, which settles on the bottom of the tank, passing through a grid just above the bottom of the tank.

The bubbles of hydrogen gas released by the reaction tend to stick to the rotating aluminium drum, so a wiper blade is provided to sweep the bubbles off the drum. The bubbles then rise to the surface of the water and are directed into the gas collection chamber by a funnel located above the arc. If the engine demand drops and the pressure in the gas collection tank rises, a sensor located in the tank causes the wire-feed control electronics to stop the wire feed which cuts off the gas production.

At first glance, a system like this appears to have limited appeal. It uses aluminium wire which requires manufacturing by a process which uses substantial amounts of energy and while a vehicle using hydrogen produced by this method will generate very little pollution, the pollution occurs at the point of manufacture. Also, the device uses a mechanical wire feed and any device of that nature will need regular maintenance and may not be 100% reliable. In addition, the aluminium oxide powder will have to be cleaned out of the generating tank on a routine basis.

But, having said all that, the system has some very significant advantages. It does not use any fossil fuel (directly). It can be readily installed in a vehicle and the consumption of aluminium wire is surprisingly low. Figures quoted indicate that typical consumption is of the order of 20 litres of water, plus one kilogram of aluminium used to cover 600 kilometers distance (1 pound per 170 miles). This is probably a good deal cheaper than using fossil fuel to drive the vehicle. However, the aluminium oxide produced by this system is

a serious pollutant as it is **highly toxic**, producing a wide range of serious illnesses, including Alzheimer's. The system is set up like this:

Another system of interest is the self-powered electrolysis system of the 1992 US Patent 5,089,107 granted to Francisco Pacheco where sacrificial anode plates of magnesium and aluminium are placed in seawater opposite a stainless steel cathode. Electrical power is generated and hydrogen produced on demand. There is also surplus electrical power available to run a standard electrolyser if so desired.

An Ultrasonic System for Producing Hydrogen.

I have been told (by a rather doubtful source) of a very high-performance water-splitting system which produces enough hydroxy gas to power a vehicle engine while only drawing 3 milliwatts at 3 volts which is a mere 9 milliwatts of power. I have never seen one of these units, and I have no evidence that the system works, other than word of mouth, so please treat the following entry as just a suggestion rather than a matter of hard fact.

The system is so interesting and simple that it is very attractive. Basically, you have two stainless steel pipes placed in a bath of tap water:

The objective is to get two stainless steel tubes resonating together at the same frequency. That is, they should both produce the same “musical” note when suspended on a thread and tapped. As the inner tube is smaller diameter, it will have a higher note than the larger diameter tube if they are the same length, so for them to match, it would be necessary for the inner tube to be longer, or the outer tube have a slot cut in it as Stan Meyer did and which is discussed in Chapter 10.

The piezo transducers are presumably glued to the cylinders, perhaps as shown above, and they are fed with a 2.24 MHz signal. The tubes need to resonate with the electronics signal, so they are ground down very slowly and carefully until they do resonate. This will presumably be at a much lower harmonic of the electronics signal, one in the standard ultrasonics range. Presumably, there will be three spacers top and bottom, maintaining the gap between the tubes. If the frequency were down in the mains region of about 50 Hz or 60Hz, then the device would just act as a water heater of the type designed by Peter Davey. At ultrasonic frequencies, the result is quite different as cavitation bubbles form in the water. A highly respected textbook on ultrasonics points out that these cavitation bubbles have a positive charge on one side and a negative charge on the other side and these charges cause electrolysis of the water surrounding the bubbles. Lots of bubbles - lots of hydroxy gas produced. So, background theory supports the possibility of this device working, however, I am not aware of anyone who has attempted to replicate it.

What we have not been told is:

1. The size, length and thickness of tubes which work well.
2. The gap between the tubes.
3. The specific transducers used in the prototype.
4. What type of spacers were used.
5. Where and how the transducers were fixed to the cylinders.

However, even without this information, this could be an interesting investigation project using absolutely minimal power at trivial voltage levels.

Valeri Ivanov's Motionless Generator.

There are other devices which are very close to the MEG construction. One of these was displayed on a Bulgarian website and it has been translated into English on the web page which is located at <http://www.inkomp-delta.com/page7.html>, put up by Valeri Ivanov in 2007. Valeri lives in Elin Pelin, Bulgaria and his motionless generator has COP=2.4 performance. Videos: <http://www.youtube.com/watch?v=7IP-buFHKKU> and <http://www.youtube.com/watch?v=npFVaeSbk1Q> are for his design, and the forum members at <http://www.overunity.com/index.php?topic=4300.135> have been attempting to replicate his device.

It is shown that an effective device can be constructed from a permanent magnet, a toroid and a laminated iron yoke. The arrangement is displayed like this:

When the input coil is pulsed with an input voltage, it causes a flux reversal in the frame around which the output coil is wound, generating an electrical output.

There is another forum related to this and the better known MEG of Tom Bearden's which can be found at http://tech.groups.yahoo.com/group/MEG_builders/message/1355 where that particular message states that Valeri's device can be made to work at frequencies as low as 50 Hz and can use standard laminated iron frame components and produces Coefficient Of Performance figures up to 5.4 (that is, the output power is more than five times the input power). A demo video is at <http://inkomp-delta.com/page10.html> but not in English.

The "MEG" Motionless Electricity Generator.

Tom Bearden, Stephen Patrick, James Hayes, Kenneth Moore and James Kenny were granted US Patent 6,362,718 on 26th March 2002. This patent is for an electromagnetic generator with no moving parts. This device is said to be self-powered and is described and illustrated on JL Naudin's web site at <http://jnaudin.free.fr/meg/megv21.htm> where test results are shown. While this device has been claimed to have a greater output than its input and an output five times higher than the input has been mentioned, I am not aware of anyone who has attempted to replicate this device and achieved a COP>1 performance, and so, for that reason, it is described in this section describing devices which are unlikely to be worthwhile for the home-constructor to attempt to replicate.

The "Motionless Electromagnetic Generator" or "MEG" consists of a magnetic ring with output coils wound on it. Inside the ring is a permanent magnet to provide a steady magnetic flux around the ring. Superimposed on the ring are two electromagnets which are activated one after the other to make the magnetic flux oscillate. This is very much like Floyd Sweet's "VTA" device.

The external power source shown above is intended to be disconnected when the circuit starts operating, at which time, part of the output from one of the pick-up coils is fed back to power the circuit driving the oscillator coils. The circuit then becomes self-sustaining, with no external input but with a continuous electrical output.

If you should construct one of these, please be warned that it should **not** be started up unless there is an external load across the pick-up coils, otherwise dangerous, potentially lethal voltages can be produced. Don't get yourself killed or injured - please be very careful.

A re-worded excerpt from the patent for this system, is in the Appendix and it gives the construction details of the prototype: dimensions, number of turns, materials used, drive frequency, monostable pulse durations, etc. The prototype produced two outputs of 48 watts for one input of 12 watts. This allowed the input power to be taken from one of the outputs, while that same output was powering other loads.

This device is essentially, a custom-built transformer with two primary windings (the oscillator coils) and two secondary windings (the pick-up coils), with a permanent magnet inserted to create a standing magnetic field through the yoke (frame) of the transformer. However, a permanent magnet has two separate energy streams coming from it. The main field is the magnetic field which is very well known. It normally flows out in every direction, but in the MEG, a very good conducting path is provided by the frame of the device. This

traps the magnetic energy flow and channels it around inside the frame. This prevents it masking the second energy field which is the Electrical energy field. With the magnetic field moved out of the way, it is now possible to tap this energy field for additional power output.

The MEG looks like a very simple device, but in actual fact, it is not. To act as a successful device with a Coefficient of Performance (COP) over 1, where the input power which is provided is less than the useful power output of the device, then Tom says that the frame needs to be made from a nanocrystalline material. This material has special properties which give the MEG it's exceptional output.

Care has to be taken with this device as the output power can be so high that it can burn the insulation off the wires and destroy the device if the output power is not controlled carefully. The output power is normally limited to a COP of 5.4 for practical reasons. If the necessary input power is taken from the output power via a rigorous control circuit which prevents runaway, then the device can provide output power while no outside input power is needed.

The output power is controlled by the waveform being sent to the oscillator coils. The power is controlled by the exact shape of the "square wave" drive:

This waveform is adjusted carefully to keep the COP down to 5.4 for safety sake. The waveform is also adjustable for frequency and Mark/Space ratio.

As it is some years since this device was patented, the question can be asked as to why it is not in production and offered for sale everywhere. The reason is that the MEG is a laboratory prototype which needs careful adjustment and tweaking. It has been replicated by others and it's performance verified as being $COP > 1$, but it is not yet ready for production where it is necessary to have the design enhanced to the stage that it can be assembled in a factory and work immediately without the need for manual adjustments. That development is in hand and may be completed in the next year or two.

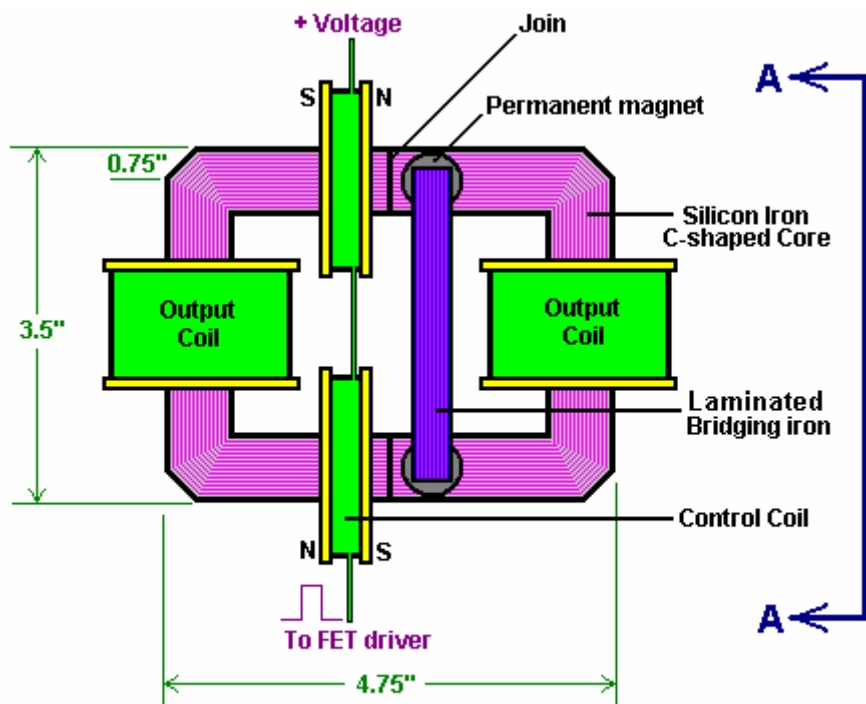

Some further explanation is in order. The MEG has an overall efficiency, well below 100% in spite of having a Coefficient Of Performance well in excess of 1. The COP of 5.4 mentioned earlier is an arbitrary figure selected by the designers to prevent the insulation being burnt off the output wires. The actual maximum output is almost unlimited, certainly a COP of 100 is perfectly possible, but quite unnecessary in practical terms.

If a standard laminated iron yoke is used for the MEG, it will never have a $COP > 1$ as input power will be needed to make it operate. The magnetic flux from a permanent magnet consists of two components. One component is rotary and it spreads out in every direction. The second component is linear and it gets swamped and hidden by the rotary field. If a toroidal yoke wound with an input winding over its whole length is used, then that traps all of the rotating magnetic field inside the toroid. The snag is that this requires considerable input power to energise the toroidal winding. The big advance with the MEG is that the inventors have discovered some standard off-the-shelf nanocrystalline materials which have the property of trapping the rotational magnetic field inside a toroid formed from them, **without** the need for any energising coil. This is a major boost to the functioning of the device.

Now, with the rotational magnetic field trapped inside the toroid, the liner field becomes accessible, and it is a very useful field indeed. It is electrical in nature. In actual fact, magnetism and electricity are not two separate things, but instead, they are different aspects of the same thing, so both should really be referred to as "electromagnetism". Anyway, the linear field is easy to access once the rotational field has been removed. All that is necessary is to pulse it sharply. When that is done, real electricity is introduced into the MEG from the surrounding environment. The sharper the waveform, the greater the additional electrical input becomes. This is what makes the MEG have a COP of say, 5.4 which is a practical working output. If the output is then manipulated to provide the input power needed for the pulsing, the COP effectively

becomes infinite as you do not have to provide any power to make it work and you have a substantial power output. The power output divided by the power input you have to provide to make the device operate, gives the COP rating, so any output divided by zero input, always gives infinity.

Dave Lawton has experimented with the MEG arrangement, using a professionally constructed custom laminated iron yoke. He found that using the standard arrangement, he found no difference when he removed the permanent magnet. Testing various configurations, he found that the most effective set-up for his components is:

Here, the drive coils are both put asymmetrically on one side of the frame and wired so that their pulses complement each other. Then two pairs of button magnets are placed on the other side of the centreline, each side of the yoke, and bridged together with two straight vertical sections of laminated iron bar. This arrangement is sensitive to the exact position of these magnets and tuning is achieved by moving the group of four magnets and two bars (effectively two "horseshoe" magnets) slightly left or right to find the optimum position. Introducing or removing these magnets then made a considerable difference to the operation of the device.

While most people find it very difficult to get COP>1 operation from the MEG, I am reliably informed that WITTS have succeeded in producing self-powered replications. There is, on the web, an exceptionally well-written presentation by Jacco van der Worp entitled "The Hitchhiker's Guide to the 'Free Energy' MEG" at <http://yowusa.com/scitech/2002/scitech-2002-06a/1.shtml> and it explains how and why it can work. By kind permission, it is reproduced here:

A Hitchhiker's Guide to the "Free Energy" MEG

YOWUSA.COM, 25-June-02

Jacco van der Worp

Foreword by Marshall Masters

This article by Jacco van der Worp a Dutch physicist, explains the "free energy" Magnetic Energy Generator MEG simply, in layman's terms. I worked closely with Jacco on this project and sent a polite request to Lee Kenny, one of the MEG principals for assistance. His quick response was controlling and reeked of paranoia. "You are NOT AUTHORIZED by MEL to publish any information regarding the MEG." (*Readers can view and comment on the full text via the YOWUSA message board post, MEG -- Masters and Kenny.*) At first, his paranoid reply puzzled me, but as we further investigated the MEG we came to understand the paranoia and it chilled our blood. Perhaps this particular genie should be left in the bottle.

My first reaction to Kenny's suppressive controlling behavior was to shoot back a reply reminding him that there is a funny little piece of paper called The Constitution. After that, the urgent paranoia in Kenny's response continued to task me.

An obvious and simplistic explanation is that Bearden et al. are busy subscribing to Yachting Magazine and setting up bank accounts in offshore tax havens for their new to be wealth. The problem is that is too simplistic an explanation, because after working with engineers for twenty-five years I've learned to recognize a knee-jerk paranoid reaction when I see one. Kenny's reply was quintessential a knee-jerk paranoid reaction. Perhaps, I would have reached this conclusion early on, were I not so enamored with the MEG technology. But as dug deeper, I found more tangible reasons for Kenny's paranoia.

The process of invention is a passionate one. At the end of the process are the hopeful financial rewards, but for something as complex as the MEG there is an equally large reward -- peer recognition. "Damn your eyes, but you did it." In this heat of invention the post reality dimensions are discussed but at a lower level and with less emphasis. I believe this is what may have happened to the MEG inventors. They simply got so carried away with the passion of invention that it clouded their view beyond the moment they would receive their patent, which in turn would embrace their paradigm shifting theories with plausibility.

However, once the patent was issued, the types of articles one would expect to see in magazines like Popular Science and Popular Mechanics failed to materialize. Further, what was made available by Bearden et al. was such geeky technobabble that it usually sails over the head of the average man. I now believe there was a reason for this.

The MEG opens a doorway into a new future, filled with new applications that will build upon the fundamental concepts of the MEG. Like the nuclear genie America unleashed upon Japan, the MEG genie offers us both a new and better world as well as a dead world all in the same breath. I believe this explains Kenny's paranoia. Now that he and his fellow MEG/MEL partners are looking at the practical applications of their invention they are starting to see it from "outside the box" as they say in the computer business. So what could they be seeing that makes them want to control the flow of knowledge about this new invention?

While the focus now is on the "free energy" application of MEG technology, its ability to interact and deform the space time continuum offers an alarming new range of applications to include: Weapon of mass destruction, interstellar space drive and time machine engine. And that is only the beginning of the hypothetical possibilities that could emerge from this paradigm shifting invention.

However, before we this genie is let out of the bottle, our elected representatives and all of us in the mainstream need to understand the MEG a little better. That is the goal of this superb article by Jacco van der Worp.

YOWUSA.COM
Marshall Masters, Publisher

A Hitchhiker's Guide to the "Free Energy" MEG

This fourth article in a YOWUSA series on the Motionless Electromagnetic Generator by Tom Bearden et al., now under patent, discusses this groundbreaking technology in non-technical layman's terms as opposed to delving deeply into the physical principles behind the MEG. Once you have finished reading the article, you will have a general idea of how the MEG works and why its inventors call it a "free energy" machine.

For those with bolder interests in the precise formulas and equations describing the MEG, those working on the project have already published several technical articles on the Internet. The best of these is a 69-page PDF file called [The Motionless Electromagnetic Generator: Extracting Energy from a Permanent Magnet with Energy Replenishing from the Active Vacuum](#). This document lays out the most basic principles used for the MEG with some graphics added in.

Getting to know the MEG

The MEG represents a revolutionary approach to generating energy in our ever more demanding economy. However, it may also become a huge financial threat to big energy companies, as Marshall Masters outlined in his article [Bearden's Free Energy MEG Destined For Chapter Eleven](#).

However, if the MEG grows into its destined role, it will conquer the market. It will do so by providing mankind with a durable and above all clean source of energy, which so far no other source of energy has achieved at an affordable price.

For the common person, the MEG is an obtuse technical wonder and understanding why it works requires one to dive headfirst into what seems to be a bottomless pool of technobabble. However, if we pare the issue down to five basic technological terms, we can create a basic understanding of the MEG.

In a MEG device there are five basic terms playing an important role in making it work. They are (energy) flux, efficiency, capacitance, magnetic field and shielding. This article will attempt to explain each MEG term simply, using everyday examples. After the basic explanation, we will explore a full analogy in the form of a rain barrel.

Flux

Flux, or energy flux to be more precise, is essentially a by-product of energy creation. For example, an automobile engine uses a mixture of gasoline and air to power the car. Older engines in particular were not extremely efficient in burning all of this mixture and the by-product is the smog that comes out the tailpipe of the car.

Modern car engines are more economical; less unburned gasoline goes out their tailpipes. However, even the most efficient cars on the road today still push unburned gasoline out the tailpipe. On top of that, part of the heat generated by the burning of the gasoline inside the engine also leaves that way. In a manner of speaking, the smog that comes out of your car's exhaust is like flux. It is a by-product of the process of creating the energy needed to make your car travel down the road.

Flux and Efficiency

Before the oil embargo of 1973, American car designers largely ignored the issue of flux by building cars with larger engines to go faster. Consequently, this fuel economy suffered from the embargo. However, in 1973 the price of fuel did not make this an important issue. Once the fuel price rose after 1973, American auto manufacturers began losing sales to foreign manufacturers who were building more fuel-efficient engines.

Efficiency

We define efficiency as the useful application of energy flow. This means that if we build a more fuel-efficient engine, it will send less unburned fuel out the tailpipe and thereby increase the number of miles we can go on the same amount of gasoline.

The part we call useful here is the energy of the burned gasoline whose heat is used to move our car. That is what we aimed for, that part divided by the total energy that could be produced from the amount of gas we used, is called efficiency.

Efficiency and Unity

Since 1973, the goal of auto manufacturers is to use the available energy in gasoline as much as possible. The most they can hope for is what is called unity. Unity means that a system can use 100% of the energy input into it. In this case, that would be the energy stored in the gasoline to generate the desired output, the output in this case is the horsepower our engine delivers to move our car down the road.

No matter how efficient the designs are in pushing toward unity, the most a system can hope to achieve with present technologies is around 30% efficiency, which is some 70% short of unity.

Unity and Closed Systems

When we commonly think of unity (100% efficiency), we also tend to think in terms of closed systems. A closed system is a system that is completely isolated from the rest of the world. In a manner of speaking, an automobile engine is a closed system. The energy released from the burning of the gasoline to extract its energy is either captured to power the car or blown out the tailpipe as wasted flux. Likewise, you continually reduce the amount of gasoline in your tank as you drive down the road. The total amount of energy that is either still stored in unburned gasoline or is moving your car along or is leaving

the tailpipe as waste flux is constant.

The essential point to keep in mind about a closed system is that it does not draw energy from the environment around it. On the other hand, an open system does draw energy from its surroundings.

Closed Systems and Open Systems

If we were to create automobiles with open systems, what would they look like? They would have the same engine, but an automobile with an open system would for example have a mast and a sail.

In this case, the driver would use the automobile engine to raise and lower the sail. The raised sail completes an open system by capturing motion energy from the wind and using it to propel the car down the road (provided the wind is with you.)

Once you have raised the sail, you can make the car go forward by angling the sail to the wind. To slow you can position the sail in line with the direction of the wind thereby neutralizing it as an active, open power system. Once you raise the sail, you do not need the car's engine for propulsion.

The essential point to keep in mind about an open system is that it draws energy from the environment around it like the sail on our modified car. In addition, it is controllable in that you can turn it on and off, just like a closed system.

Open Systems and the Coefficient of Performance (COP)

Because the auto sail is not limited to the energy of the fuel in the gas tank (which can never exceed unity or 100% efficiency), an open system (portrayed here by the auto sail) can in fact exceed unity. In other words, it can obtain more than 100% efficiency from the energy system it is interacting with, which in this case is the wind. So how do we measure systems that can achieve more than unity?

The term Coefficient of Performance (COP) compares the amount of energy input into a system versus the usable amount of energy output by the same system. For example, if using the engine in our auto to raise the sail requires one unit of energy and that when the sail is raised it generates or gathers 8 units of wind motion energy, the Coefficient of Performance is 800%. Another way of expressing this is 8:1, where 8 is the useful energy available and 1 is the amount of energy inserted into the system to trigger the generation of usable energy.

Coefficient of Performance and Capacitance

In our car example we used a sail to propel our car to achieve an 8:1 COP. Could this work with larger systems? For example, could it work with trucks as well? We already know that sails were used to propel huge wooden sailing ships centuries ago.

Let's go back in time to sailing ships for a moment. The builders of these great ships knew that the more and bigger sails they added to their ships, the faster they would go. However, great expanses of water surround that ship on the ocean. With this in mind, let's see how this applies to using sail power to propel cars and trucks.

Because cars and trucks travel in close proximity to each other and in the same direction on a highway, the amount of wind energy available in the open system must be divided amongst the various vehicles. Consequently, those in closest proximity to the wind direction will bleed off wind power from those ahead of them. In essence, they literally steal each other's wind.

In terms of capacitance, the essential concept here is that open systems may not be unlimited systems. In the case of our auto and truck sails, the proximity and number of sails accessing the same open wind system for energy will drain the open system. In other words, even if an open system is free, capacitance tells us that there is only so much of it to go around.

At this point, we've discussed some general terms used with the MEG. Now we're ready to discuss terms that are more specific to the MEG, beginning with fields.

Fields

In very simple terms, a field is any mechanism that serves as a means to an end. In the car example, we used a sail as our field, in that it gathered energy from the open wind system.

Unlike the sails we use as fields to capture the energy we need to propel our cars, in terms of the MEG, we must use something called a magnetic field.

Magnetic Fields

In the case of the auto sail, we used our sail as a field to pull energy from the open wind system around us so that we can propel out autos. The energy we needed was stored inside the wind.

With the MEG, the energy source we need to tap is not the wind, but electromagnetic forces of the universe that are just as omnipresent as the wind is on Earth, if not more so.

What the sail and the MEG have in common concerning the fields is that they must control their fields in order to prevent undesirable side effects.

Looking at our auto sail example, we attach lines to the sail and boom to control the trim of the sail so that it captures as much energy as possible without overstressing the sail and causing damage. Hence the popular sailing term, trimming the sails. Likewise, untrimmed sails can be dangerous, presenting a hazard to systems such as the boom and mast, or to the sailor if the wind moves the sail and boom violently across the ship, upsetting the balance of the ship.

In a manner of speaking, the MEG uses something called shielding to achieve the same thing as controlling the trimming of the sail if you will. Without it, violent effects may damage its surroundings.

Magnetic Fields and Magnetic Shielding

With the MEG, the magnetic fields are very powerful and must be controlled tightly at all times in order to prevent them from creating havoc in the space around them. This is why the MEG needs to use magnetic shielding.

The most important concept of magnetic shielding is that it serves as a safety control for magnetic fields by containing and minimizing their negative effects.

The Rain Barrel Example

At this point, we've covered all the bases with the exception of the magnetic vector potential, which forms the crux of the MEG theory. To help you to understand the complexity of this concept, let's first review what we have covered up to this point within the context of a simple rain barrel system. The reason for this is that one may understand the MEG magnetic vector potential more easily from a systemic viewpoint.

Flux

Some of us may have tried the following as kids or even later in life. If we take a barrel filled with water (or a gas tank filled with petrol) and we want to take some of that out, we do not have to suck it all out ourselves.

We take a piece of hose; simple garden hose will do, and stick it into the reservoir from which we want to take the liquid. On the outside, we lower one end of the hose a little lower than the opposite end sitting inside the tank. Then we gently suck on the hose (let's keep to water from here if only for the sake of taste) and the fluid will start to flow. Once it does, it will continue to flow until the other end of the hose inside the tank is no longer submerged. Therefore, with only a little effort we move a lot of fluid out.

The mechanism that makes this work is called the capillary effect. In other words, the weight of the column of fluid in the hose with a height equal to the difference in height of the two ends of the hose is providing the force that is needed to keep the fluid moving. However, what we do know is that the water barrel will run empty if we just pour it all out.

On the other hand, the MEG draws energy from a 'barrel' that fills itself right back up! So it never runs empty! If you repeat the stimulated energy flow out of the MEG, energy flux will come out of it continually; it will not run dry like our rain barrel.

Therefore, a proper way to describe the MEG therefore in terms of this example would be a rain barrel into which more rain would fall the instant that that one draws water from it. Once you start the water flowing through the hose, the rain starts falling into the barrel and replaces the water you're pulling out at a similar pace.

For this reason, a MEG-style water barrel will never run empty and the water will flow forever out through the hose once you have brought it in motion because the MEG is an open system, which brings us to the next point of consideration, what efficiency vs. COP means for our rain barrel.

Efficiency and the Coefficient of Performance

For the purpose of our rain barrel example, the term "efficiency" can be defined by the amount of water we can pull from the barrel by drawing it into motion with the siphon hose.

With the closed system water barrel, we learned that a closed system is isolated from the rest of the world, so no rain comes falling in from above to replace what we're taking out. In this case the best we can do is position the hose at the very bottom of the barrel on the inside and while letting it hang even lower on the outside. By doing this, we can siphon all of the water out of the barrel, which gives us maximum of 100% of the water. This 100% of efficiency is called "unity."

Keeping the unity of our closed rain barrel system in mind, let's shift back to our open system variant.

The moment we begin to siphon water from the open system rain barrel, fresh rainwater falls in through the open top of the barrel. No matter how much water we siphon from our open system water barrel, enough new rain falls through the top to replace what we are taking about.

Therefore, put in motion a never-ending stream of water with our open system rain barrel we can obtain results greater than that of unity. This is what the Coefficient of Performance (COP) is about. We use it to express the output result, which is greater than what we put in. Ergo, the COP for the open system rain barrel can exceed unity (100% efficiency) whereas the close system rain barrel can only hope to achieve unity. So then, what happens if we increase the size of our rain barrel?

Capacitance

Aside from the direct effect of having more water by increasing the size of our water barrel and siphon hose, there are indirect effects as well and they need to be carefully considered.

For starters, if we make our barrel bigger as well as our siphon hose what will that mean for us? Given that we'll be using a bigger hose to siphon out more fluid, we'll need a stronger suction force to begin with. We can do that simply (provided we have the lung power) without requiring a scaling-up of the entire system.

However, if we drain more water per second from a bigger barrel (e.g. the size of a lake) and we want it to keep running, it will have to rain harder to replenish the water that we take out and rainfall is bound to a natural limit.

At a certain barrel and hose size, not even a tropical storm will provide enough rain to keep the water level up and the system will start to collapse. On top of that, a normal barrel stands on a support structure. The bigger the barrel, the harder it will be to find a place for it to stand and remain standing. Otherwise it might fall over or break. So, how do we keep our bigger barrel from coming apart?

Fields and Shielding

If the barrel gets really big (let's assume for a moment it is the size of Lake Superior) and we start siphoning water out of it at the pace of four times the total water flux of the Sault Ste Marie Canals, then the water level will take time to readjust for the water poured out. The most important field in action here is the siphoning process, powered by gravity, which results in the water flow out of our bigger barrel lake. (Yes folks, now we're talking at a planetary scale.)

Normally, water level is horizontal (allowing of course for the curvature of Earth on a larger scale). However, if the pace of siphoning gets high enough, the normal water flow will become incapable of correcting the level quickly enough.

A permanent difference in height of the water level from one side of the lake to the other will arise. In that case stopping the siphoning action will not result in an immediate stop in water flowing towards the siphoning point. A sudden stop in pouring from a lake-sized barrel will cause at least a small tidal wave. The bigger the level difference across the lake, the worse the tidal wave will turn out. Although that looks like another field in action in the big barrel system, it isn't. It is a self-correcting mechanism for the lake surface after it has been disturbed.

In simplistic terms, what this all boils down to is that the flow energy like the flow water through our water barrel system represents a field. As a field increases in size it can likewise destabilize in greater amounts as well. Therefore, if we wish to increase the size of our fields we must find ways to shield them from those things, which could destabilize them.

Fields and Shielding

If our normal-sized rain barrel overfilled with water it could start to leak. In such a case, we would need measures to prevent a gushing flow of rainwater from damaging the immediate surroundings in a flood.

On the other hand, with our lake-sized version of water barrel we would need dikes to surround our lake to keep it from overflowing onto the land around it.

This flooding finds its cause in a pace difference between the raining in and pouring out of the water. These dikes must of course be able to withstand small tidal waves that emerge due to the starting and stopping of the siphoning action. In very simple terms, this is called shielding.

Up to this point, we've covered the most essential concepts we'll need before we tackle the big one -- vector potential. This is an important yet complex concept but it goes to the very heart of what a MEG is why it can do what it does.

MEG Components and Layout

The picture below, taken from the abstract by Magnetic Energy Limited as it published on the Internet. (We've added the colored placeholders to make it easier to view.) This illustration shows the basic layout of a lab prototype of the MEG used to successfully demonstrate the theory.

Figure 17. Diagram of laboratory test prototype.

- **PERMANENT MAGNET (A):** The most important element is the permanent magnet sitting in the middle of the schematic picture. The magnetic field lines come out of that bar magnet at the top and bottom side (in this picture). This magnet is what helps drive the entire machine.
- **NANO-CRYSTALLINE FLUX PATH AND CORE MATERIAL (B):** Instead of freely 'circling' from the North Pole of the magnet to the South Pole they enter a 'nano-crystalline flux path and core material.' That material captures all of the magnetic field of the permanent magnet, so that no magnetic field is present free in the air any more.
- **COLLECTOR COIL (C):** The collector coils are the points where energy can be tapped from the MEG.
- **ACTUATOR (INPUT) COIL (D):** The actuators are the points of input of energy to put the much larger amount into motion.

To compare it to the rain barrel, the actuators are your mouth drawing water through the hose. The collectors are the hose ends hanging out of the barrel that starts to pour once you've generated a capillary with your siphon hose. And finally, the magnet and the coil containing the magnetic field are the barrel reservoir containing the water.

How the MEG Works

Now we come to the crux of the whole system, the reason why it works in the first place. The driving force in our large, lake-sized rain barrel was the force of gravity. That made the water that falls at some distance away from our hose move towards the initial siphon point and in turn caused the water to run through the siphon. In this case, gravity is the restoring force of the water level of our lake-sized rain barrel as it makes the water level go horizontal again.

This force and the correction mechanism attached to it have an equivalent in the magnetic arena. That force is the magnetic vector potential. If we look at the MEG, we see that it converts an energy flux that was stored in such a vector potential outside a closed magnetic field path. (Whoa, wasn't that a mouthful. Let's break it down into more simpler terms.)

OK, So What is a Vector Potential Anyway?

To explain vector potential, we need to use something other than a rain barrel, but it must be familiar so why not the energy we use in our homes to run our computers, hairdryers, etc.

We all know about the electrical potential across the two wires of a wall outlet. This electrical potential is what makes a light bulb burn. If we're not careful with the outlet we could also find ourselves flat on our back as our family members frantically call for an ambulance. Thankfully though, the US, the electrical potential is 110 volts, which was chosen because it is not as lethal as the 220-240 volts standard found in most of the other countries in the world.

However, if we combine the numerical value of this electrical potential with a direction, we have a vector potential. In the case of our 110-volt outlet, if we change the direction from say the horizontal to the vertical, we can double our potential to 220 volts. Therefore, direction is important for the creation of any magnetic field; they all emerge from a magnetic vector potential where direction plays a critical role.

The following illustration compares the MEG with our rain barrel example for a very general layman's understanding of how the MEG works and why the magnetic vector potential is so important. (Please keep in mind a precise explanation would require an article several times the size of this one, so we'll just paint our picture with broad liberal brush strokes for now.)

- (A) An outside reservoir waits until the system is brought into motion and then starts to work to restore the balance that is broken by sucking the siphon hose. For the rain barrel it is the rain filling the barrel back up, for the MEG it is the vector potential converting its energy into magnetic field inside the closed path.
- (B) This adds an extra field to the magnet field inside the closed loop.
- (C) In essence the actuators work like the siphon hose in our rain barrel example and by changing the direction of the water it creates an outside vector potential.

- (D) Consequently, the closed path starts to interact with the magnetic field inside, to compensate for the change in the situation. It gives energy to the magnetic field inside the closed path.
- (E) We can then tap that energy from the collectors and we find that more electrical energy comes out the collectors than the amount we put in through the actuators. So energy from the vector potential field outside the closed path is 'flowing towards the siphon' to correct the 'field level' again. If we lead part of this energy back into the actuators again, the rest of it is free flux! Free flux?

With the MEG energy flux actually becomes the result product or output instead of a waste by-product as with fossil fuel powered systems like car engines. What used to be waste is now useful output, just like today's electricity drawn from the net to light our houses.

In that respect, the MEG forms a new way of looking at energy flux and if you happen to install a MEG next to your home, it will require far less energy to provide you with far more electricity. Consequently, your energy costs will come down considerably.

Why the MEG is Commonly Misunderstood

The MEG uses an input energy flux to convert a far greater amount of thus far unusable energy flux into a controllable and more convenient form. This can leave some folks scratching their heads because this is a whole new twist on flux. For those who are familiar with the principles of conservation of energy this represents a paradigm shift in thinking that can defy years of heavily instructed thought about closed systems. And here is the rub. The rigid principles of conservation of energy apply only to closed systems such as automobile engines, whereas the MEG is an open system.

Because the MEG is an open system, it can turn flux into output because it is a system out of balance with the world around it and therefore constantly interacting with the environment around it! This way, it may result in a COP that is far greater than unity.

Another factor that makes it difficult for conventional thinkers to understand the MEG is that it does not use the Lorentz Gauge.

When Tom Bearden and his team of researchers discovered the principles behind the MEG when they chose to omit a commonly known calibration of an electromagnetic system, the so-called Lorentz Gauge.

The Lorentz Gauge is essentially a free choice of values for given parameters of an electrical system; this free choice makes mathematics simpler. At the same time however it discards a range of interesting (as it turns out now) solutions to a set of equations describing the same system. This range is the range of non-equilibrium states.

By keeping the MEG just off-equilibrium (out of balance) all the time, we can use it to pull a tremendous amount of energy out of a so far unusable reservoir into a convenient form. In essence, this is what the MEG is about.

Potential Problems with the MEG

We know that the MEG works, but it is also of interest to see just how much it can do. Most of you will likely be interested to know if a MEG can power a home. Can we scale it up without a limit, or could one such device even power a city?

The scale of many devices is only limited by practical design questions. The MEG needs a permanent magnet as well as a nano-crystalline material completely confining the magnetic field loops that leave this magnet. It also needs input and output coils. Electrical currents running through wires will produce heat, which will have to be dealt with at a high enough pace, but other than that, the potential size and productivity of the system is virtually unlimited. This type of generator should a priori be scalable to city-block level.

There are, however, possible side effects to its operation, which we want to take a closer look at before starting to operate a MEG for a city.

A few problems might exist for the MEG. Right now, it is uncharted territory, but we need to consider the possibility that above a certain level, the vector potential field cannot rearrange its energy fast enough for the working conditions to remain intact, thereby causing the MEG to fail. To fully illustrate this possibility, let's revisit some of the basic terms we discussed earlier in this article.

Magnetic Fields

The energy stored in the magnetic field and the vector potential field may interact with conducting materials outside the MEG as well, generating secondary magnetic fields and electric currents.

There's more. As energy leaves its surroundings, new energy comes flowing back in. We do not know if the pace of that is bound to a limit. It may have side effects that are currently unknown to us. Some pessimistic reactions have even spoken of an alteration of the space-time continuum surrounding the MEG. That would be a serious consequence indeed, but we have seen no proof of it so far.

Besides the argument presented above there is the coil material that is supposed to fully contain the permanent magnet's field and the additional field generated during interaction. A bigger MEG will also need a stronger magnetic field. Just how much can the coil material take before the field starts to break up the material itself? This bigger MEG may need superconducting materials to gain that stronger magnetic field. There will be additional conditions that are imposed by that material. We need to maintain that superconductivity to prevent damage to the material.

However, stronger magnetic fields do pose a health risk. For this reason, most people do not want to live under or very near high voltage power lines. They carry strong electromagnetic fields around them as well. It is however possible to shield magnetic fields.

Shielding

If someone were to switch off the input signal to a large MEG, the field may not die away instantly, which would result in a field spike as it follows suit to the signals. Then EM pulses may arise, which are (very) destructive to all electronic equipment. These EM pulses are so destructive in fact, that some nations have conducted extensive research into their possible application as a weapon.

A Faraday cage would form the "dike around the lake" for the MEG. This is a metal case enclosing the magnetic field plus the MEG completely. With the exception of strong EMP effects it will keep a semi-steady field contained so that no outside negative effects will occur. So in the course of normal operation, the MEG can be shielded quite easily. The worrisome moments occur when switching the MEG on or off. How will the shielding affect the ability of the vector potential field energy to replenish itself as energy leaves the unit?

We Need to Proceed With Caution

Concluding, we can say that the MEG is a means to pour energy from a tremendous reservoir with remarkable little effort. The result is almost limitless energy at practically no cost. The only drawback known in the current state of research is that on a large scale nasty, hard to control side effects may rear their ugly heads. Therefore while the MEG represents a ground breaking and innovative new technology it should not be rushed to market without exhaustive testing.

The Devices of Hans Coler

Hans Coler developed a device which he named the "Stromerzeuger" which consisted of an arrangement of magnets, flat coils and copper plates with a primary circuit powered by a small battery. The output from the secondary circuit was used to light a bank of lamps and it was claimed that the output power was many times the input power and could continue indefinitely.

The apparatus principally consists of two parallel connected spools which being bi-filar wound in a special way, are magnetically linked together. One of these spools is composed of copper sheets (the spool is called the 'plate spool'). The other one is made of a number of thin parallel connected isolated wires (called 'spool winding'), running parallel to the plates, at small intervals. Both spools can be fed by separate batteries (6 Volt, 6.5 Ahr were used). At least two batteries are needed to get the apparatus operating, but subsequently, one battery can be removed.

The spools are arranged in two halves each by the bi-filar windings. The plate spool also contains iron rods with silver wire connections. These rods are magnetised by a special battery through exciter windings. Electrically, the exciter winding is completely isolated from the other windings. Hans said that the production of energy takes place principally in these iron rods and the winding of the spools plays an essential part in the process.

It should be mentioned that the spool circuit is powered up first. Initially, it took a current of 104 mA. The plates and exciter circuits are then switched on simultaneously. When this is done, the current in the spool circuit dropped from 104 mA to about 27 mA.

It is suggested that an electron be not only regarded as a negatively charged particle but also as a South magnetic pole. The basic Stromerzeuger element is that of an open secondary circuit, capacity loaded, inductively coupled to a primary circuit. The novel feature is that the capacities are connected to the secondary core through permanent magnets as shown here:

It is claimed that on switching on the primary circuit, “separation of charges” takes place with M1 becoming positively charged and M2 becoming negatively charged and that these charges are “magnetically polarised” when they formed, owing to the presence of the magnets. When the primary circuit is switched off, a “reversing current” flows in the secondary but the magnets “do not exert a polarising effect on this reversal”.

Two of the basic elements shown above are placed together making a double stage arrangement with the copper plates close together.

Note that the M1 coil is reversed. The magnets carry current and so it would be reasonable to presume that they are iron magnets rather than ferrite, iron magnets being common sixty years ago, combined with the fact that ferrite magnets do not conduct current and neodymium types were not available in 1925. The secondary windings are both exactly equal and “wound in a direction such that, on switching the primary coil on”, the electrons flow from P1 to P2 and from F1 to F2. Again, this is a most peculiar statement as the direction of electron flow is not affected by the direction of winding of the coil, which suggests that the person making the report knew almost nothing about circuitry. It is highly likely therefore, that the brief report which has survived to today, is very vague and lacking in the essential details, the diagrams not indicating the bifilar windings and straight wire lengths mentioned earlier.

One of the very unusual statements made is that the F1/F2 circuit only induces the effect and that the excess power is drawn from the P1/P2 circuit. This is the basic working arrangement. More of these double stages can be added to provide higher outputs, with their outputs connected in parallel for greater current.

The original document, with masterly ambiguity, states that to make this arrangement, two of the original circuits are placed one on top of the other and then promptly draws the arrangement, showing the M1 magnet poles reversed, which of course, contradicts what has just been stated. So, it is not clear if the diagram or the statement is correct, but the likelihood is that the diagram is right.

For there to be any kind of continuous output from a transformer, the input cannot be DC in spite of the fact that dry-cell batteries were used to power the circuits (even though the output could be as high as six kilowatts). Coler stated that his research indicates that permanent magnets actually oscillate at about 180 kHz. If that is correct, then that could account for the magnetic induction produced in the circuit. If that is not what is relied on in this circuit, then the batteries have to be connected and disconnected continuously, and the technology being simple at that time, it seems likely that a relay would have been wired to self-oscillate as in the early electric bells. While that arrangement could have been used just to connect and disconnect the batteries with a relay contact, the relay coil will have generated high-voltage sharp pulses, generating short magnetic pulses of the type which causes an inflow of cold electricity into the circuit from the local ambient background.

Alternatively, although it is not mentioned or suggested, the connection could have been made using a relay which had only one contact, in which case, the back-EMF of the relay coil may have fed high-voltage pulses directly into the circuit. This is, of course, just ill-informed speculation. The arrangement **might** have been:

In each case, the battery current flows the normally closed relay contact, powering the relay winding, which opens the switch contact, disconnecting the relay and so closing the switch contact again. This causes rapid pulsing of the battery voltage and the relay coil generates high voltages, typically of some hundreds of volts. If the circuit connection is as shown in the first arrangement, then when the relay switch opens, high back-EMF voltage pulses will be fed to the circuit. On the other hand, if a relay with two separate contacts is used, the second relay switch contact can be used to connect the battery to the circuit and disconnect it again in a very rapid sequence. There is a group of people at <http://tech.groups.yahoo.com/group/testatika/> who are working towards making an operational version of this device. Information on the Coler devices is presented clearly at <http://rimstar.org/sdenenergy/coler/index.htm#STROMERZEUGER>.

Chapter 14: Renewable Energy Devices

Heaters.

The devices described here are not “free-energy” devices as such, but in spite of that, it is an area of considerable interest to many people, and the subject is included here because of that.

If you do not live in an urban area, then a solid fuel stove can be an economic solution, especially if the fuel can be collected free from wooded areas. Stove design has advanced considerably and it is now possible to make a simple stove with very high efficiency and very low emissions as shown here:

Although this stove is a very simple construction, it's efficiency is very high indeed. The best fuel is made of smaller pieces which rest on a simple shelf. Branches work better than large pieces of wood as the consumption is more complete. As the fuel is consumed, it is pushed further into the stove, which gives the user an appreciation of the rate of consumption. Having the fuel resting on a shelf has the major advantage of allowing air to flow both above it and below it, which gives improved combustion. The operation is said to be so good that there is virtually no residue and no emissions.

Again, if land space is available, a solar oven (or Stirling motor) can be used, either to store energy for later use or generate heat for cooking or home heating, as can hot-water solar panels. However, it is only realistic to consider the application to be during the night in a built-up area with little or no spare space for equipment.

The Wood-Gas Stove.

There is another very effective type of wood-burning stove. There are several commercial versions of this stove on sale, but most of them use an electric fan to get the effect which is produced automatically by this design. This design has been replicated by Alberto Feliciano and found to be very effective in operation. It causes a load of wood which would normally burn up in fifteen minutes to burn for a whole hour, putting out a much greater amount of heat. The design is very straightforward. There is an outer drum which has a solid base, and the opposite end removed entirely as shown here:

A ring of ventilation holes is drilled around the whole of the bottom edge of the drum and threaded rods are run through the drum. These support a circle of wire mesh which forms a supporting shelf.

A smaller drum then has both ends removed, to form a cylinder. This cylinder is to fit inside the outer drum. It rests on the mesh shelf of the outer drum. This cylinder has a ring of ventilation holes is drilled around the whole of its upper edge as shown here:

A third drum which is only slightly smaller than the outer drum is cut down to make a cap for the inner cylinder. This cap is not tight-fitting, but it effectively closes off the top of the gap between the sides of inner cylinder and the sides of the outer drum:

This cap has a circular hole cut in it, and this hole is only slightly smaller than the diameter of the inner cylinder. It is supported by the upper lip of the inner drum but the hole is large enough that it does not obstruct the flow of heat up through the top of the inner drum. These three pieces fit together like this:

Wood of any type, branches, sticks, firewood, etc. are placed inside the inner cylinder and set alight. Initially, the flames come out of the top of the stove as you would expect, but after a few minutes, the combustion alters completely. The burn now becomes that of wood-gas rather than of the wood itself. The wood is slowly converted to charcoal and the gas released by this process burns with greater heat than the wood would give as well as burning for a much greater length of time. This stove design can be made in any size. Small versions get a burn length of about three times that of the wood burning in the open air, while large versions can reach four times the burn length.

Flames no longer come out of the top of the stove, but instead, they come out of the ring of holes around the base of the outer drum. The process is like this:

A high-temperature gas burn takes place in the centre of the inner cylinder. This pushes heat out through the top and the bottom of the inner cylinder. The heat flowing out of the top is used for heating or cooking as before. The heat flowing out of the bottom gets diverted around the outside of the inner drum, flows upwards, is caught by the cap and fed back into the inner cylinder through the ring of holes at the top of the inner cylinder. This raises the temperature of the gas burn even further and it augments the heat coming out of the top of the stove. The result is a very hot burn which goes on far longer than would happen if the same wood was burnt on an open fire or in a single open drum. When the wood reaches the end of its burn cycle, it can be replaced by feeding new wood through the hole in the cap which rests on the inner cylinder. The stove will need to be emptied of ash from time to time.

Solid Fuel Producing Electricity

We then to think of small-scale solid-fuel burners as providing heat and perhaps a little light as well. The people in Siberia don't think like that and they produce a range of (just) portable solid fuel stoves which

provide heating, cooking and 12-volt electricity up to 50 watts. While 50 watts doesn't sound like much, it is a major amount when there isn't any at all available. A small inverter provides mains AC power for smaller appliances:

If it is still there, the video of this is at <http://www.youtube.com/watch?v=2Za98e7-Mxg&feature=related> and the manufacturers (http://www.termofor.ru/eng/products/for_heating/normal_pg/index.html) show a video of this stove design being used in a snow-covered wood at -32 Centigrade temperatures, giving about +35 degrees Centigrade inside the tent. Mind you, weighing in at 54 kilograms which is a whopping 120 pounds or so, this is not a back-packing solution for camping trips. Sales outlets are in Siberia, New York, Australia, Kyrgyzstan, Ukraine, Belarus, Kazakhstan and Latvia at the present time.

The HHO Gas Option.

One significant advantage of this design is that less wood is needed for any give heating or cooking application and there is very little smoke or soot produced which is a distinct advantage for a person using the stove for cooking and standing nearby during the cooking process. This can cause a major medical improvement as smoke inhalation for women who need to undertake long periods of daily cooking using wood as a fuel, are liable to suffer serious breathing problems as a result.

Electrical heating, while very convenient, is usually expensive, and it often seems that the effectiveness of an electric heater is not directly related to its power consumption. In theory it definitely is, but in practice it just does not seem that way. There are other alternatives.

One of the other documents in this set, shows how to construct a Stanley Meyer style electrolyser which uses ordinary tap water and splits it into burnable fuel using just a low power electrical input:

The difficulty in creating a heating system which uses the gas produced by this unit, is in the very high temperature produced when the gas is burnt. Stan overcame this problem with by designing a special burner which mixes air and burnt gasses in with the gas before it is burnt. That lowers the flame temperature to a level which is suitable for heating and cooking:

While this looks a bit complicated, it's construction is really quite simple. The combination of the Meyer electrolyser and Meyer burner form a system which has the potential of being operated from a solar panel and battery as shown here:

A system like this needs extreme care as the hydrogen / oxygen ("HHO") gas produced is explosive. So:

1. It is very important that the electrolyser has the ability to provide sufficient gas to keep the flame(s) sustained.
2. The electrolyser must be fitted with a pressure switch, typically operating at 5 pounds per square inch or so. This is included so that should the gas usage drop, then the drive from the electronics is cut off to stop further gas production, and incidentally, stopping the current draw from the battery.
3. It is absolutely essential that there be a flame-operated valve on the gas supply line to the burner, so that should the flame go out for any reason whatsoever, then the gas supply will be cut off. This type of valve is common on town-gas operated fires for use in homes.

Henry Paine's Patent.

There is an alternative method which it is claimed can convert the explosive HHO gas into a much more docile fuel, more suited to conventional burners and stoves. It must be stressed that this system is over 120 years old and it should not be used until you have carried out careful tests on it. David Quirey has been using this technique successfully for more than twenty years now. The method was patented by **Henry M. Paine** in US Letters Patent No. 308,276 dated 18th November 1884 and it is very simple:

The idea is to bubble the HHO gas produced by electrolysis of water, through a liquid hydrocarbon such as turpentine or acetone. The bubbler should have a large number of small holes in the incoming tube, so that a very large number of small bubbles of HHO gas pass through the hydrocarbon. This brings the majority of the HHO gas into intimate contact with the hydrocarbon and the process is claimed to convert the HHO gas into a new variety of gas which is not explosive, can be stored for later use, and which burns with the same characteristics as coal-gas ("town gas").

The Heaters of Sang Nam Kim.

Mr Kim of Korea also proposes methods of using hydroxy gas for heating and using Henry Paine's hydrocarbon bubbling method. He has four patents on the subject of heating:

US 6,397,834 in June 2002 - Heating Furnace
 US 6,443,725 in September 2002 - Energy Generation
 US 6,761,558 in July 2004 - Heating Apparatus
 US 7,014,740 in March 2006 - Electrolyser

The first of these shows his method of getting both beneficial radiant heat and convention heating from a stone construction like this:

This unit is intended as a seriously powerful heating source for a minimum of one room. Mr Kim quotes a hydroxy gas requirement of 30 litres per minute which is a very considerable amount, and if the gas is produced by electrolysis of water at Faraday efficiency, it would need a current draw of 4.2 kilowatts. There is every indication that Mr Kim's method of electrolysis is low efficiency as his latest patent shows a radiator and fan:

It is virtually certain that there will be a high proportion of hot water vapour mixed in with the gas which is being burnt and that will reduce the explosive nature of the gas to near zero. It also means that the actual volume of hydroxy gas is likely to be well below the 30 lpm quoted by Mr Kim.

Mr Kim also shows a burner intended for use with an existing furnace. He remarks that the outer casing gets to be red hot, running at 1,000°C or more, and so any replication of his design should be treated with care when mounting fixtures are being constructed. In this design, Mr Kim uses the Paine technique and recommends bubbling his hydroxy gas through hexane liquid (C_6H_{14}) where 0.3 litres of hexane per hour gets burnt as well as the hydroxy gas. He rates the hydroxy gas requirement of this burner as being 20 lpm, which at Faraday efficiencies, represents 2.8 kilowatts of electricity, although as mentioned before, it is likely

that the actual amount of hydroxy gas in his 20 lpm volume is much lower than he thinks, and so will have a lower electrical requirement when using a more electrically efficient electrolyser. His burner is like this:

Mr Kim believes that the hexane prevents flashback ignition. He does not appear to specify the heating material inside the burner but it is probably stainless steel wool. He speaks of gas pressures of 1 Kg per sq. cm., which, if my calculations are correct is 14.22 psi. which is not possible for 100% hydroxy gas as it will explode spontaneously at 12 psi. due to its high energy state and electrical charge.

He states that the secondary flames at the top of the unit "burn with a blue flame colour" and that is different to the flame colour lower down. Mr Kim believes that the hydroxy burnt at the bottom of the burner forms water vapour which is then split into hydroxy gas again by the very high temperature and that is the reason for the blue flames at the top. Personally, I don't believe that this will take place and that the effect may have a good deal to do with the hexane liquid being burnt. However, this burner design appears to be a good one for lower grades of hydroxy gas.

If a higher grade of hydroxy gas is being used, please be aware that a hypodermic-size tiny burner orifice will be needed to avoid flashbacks and no commercial flashback arrester will work reliably with good quality hydroxy gas on every occasion and so a bubbler is absolutely essential.

Heating With Electric Power.

Electric power is very popular for heaters. However, with most appliances, it is a very expensive form of heating. There is a technique which is reputed to improve the efficiency and lower the cost of electric heating. This method involves rotating a cylinder inside an outer cylinder and filling part of the narrow space between the cylinders with some variety of light oil.

Eugene Frenette's Patent.

This method has been patented more than once. In 1979, Eugene Frenette was granted patent 4,143,639 where a single motor is used to rotate the drum and power a fan to boost the motion of the hot air:

It is not immediately obvious why this arrangement should work well, but it appears that it does. As the inner drum spins around, the oil rises up between the two inner cylinders. It lubricates the bearing under the rotating drum and the rotation causes the oil to heat up. This heats the middle cylinder and air being drawn up around it by the action of the fan blade, is also heated before being pushed out of the top of the heater. After a few minutes, the outer housing becomes so hot that the thermostat attached to it, cuts off the electrical supply.

The heater does not stop heating at this time as air continues to circulate through the heater by ordinary convection. In my opinion, it would be more effective if the fan motor were operated independently and did not cut off when the heater reaches its operating temperature.

Eugene Perkins' Patent.

Very similar systems were patented by Eugene Perkins: January 1984 patent 4,424,797, November 1984 patent 4,483,277, March 1987 patent 4,651,681, October 1988 patent 4,779,575, and in January 1989 patent 4,798,176.

His first patent shows a horizontal drum which is completely immersed in the liquid:

This calls for a much greater accuracy of construction in that the liquid has to be contained even though it has a rotating shaft running through the housing. This device pumps the heated liquid through central-heating piping and radiators.

In his later patent of the same year, he shows a modified version with two drums and an impeller:

The "heat exchanger" is a radiator or set of radiators.

He then progressed to a system where the shaft rotation forces the liquid to be expelled through the tips of arms radiating out from the centre of the impeller hub:

Here, the liquid is forced into a small space between the rotor and its drum housing. This system has been used very successfully for water heating and some measurements indicate that it is at least 100% efficient and some people believe that it is well over the 100% efficiency, though they don't want get drawn into long discussions on methods of measurement. It is sufficient to say here, that this method is very effective indeed.

Frenette Variation: The Frenette heater design shown above with its two vertical cylinders, is not the easiest for the home constructor unless one of the cylinders (presumably the inner one) is constructed from steel sheet, as it is difficult to find two commercially available steel cylinders of just the right relative size to produce the wanted gap between them. A much easier variation replaces the inner cylinder with a stack of circular steel discs. As these can be cut from 20 gauge steel sheet fairly readily by the home constructor, or alternatively, cut by any local metalworking or fabrication company, any available size of outer cylinder can be used and the disc diameter chosen accordingly.

The discs are mounted about 6 mm (1/4") apart on a central steel rod which is rotated in order to drive the discs through the oil contained inside the body of the heater. While this looks like a Tesla Turbine, it is not because the spacing of the discs creates a different effect. The wider disc spacing creates shear as they spin through the surrounding oil, and this shearing creates a high degree of heating. It must be remembered that this is a heater, and the outer canister gets very hot during operation (which is the whole point of the exercise in the first place). For that reason, oil is used as a filling and not water, which boils at a much lower temperature. The larger the diameter of the canister and the greater the number of discs inside it, the greater the heat developed.

To ensure that the discs do not come loose during prolonged operation, a hole can be drilled through them just outside the area covered by the locking/spacing nuts, and a stiff wire run through the holes and the ends either welded to the central rod or pushed through a hole drilled in it and bent over to hold it in place. The heat of the cylinder can be circulated by attaching a simple fan blade to the spinning shaft. This blows air down the hot sides of the canister, moving it towards the floor which is the most effective place for it circulate and heat the entire room.

As the discs spin, the oil is pushed outwards and moves upwards, filling the top of the canister and building up some pressure there. This pressure can be relieved by running an external pipe from the top of the

cylinder back to the bottom, allowing the oil to circulate freely. This has the decided advantage the circulating oil can be passed through a radiator as shown in the following diagram:

The central rod can be rotated by any convenient motor, conventional, Adams type, pulse-motor, permanent magnet motor, or whatever. An alternative to this style of operation, is to use the rotating motor to spin a ring of permanent magnets positioned close beside a thick aluminium plate. The eddy currents cause very strong heating of the aluminium plate which then can have air blown across it to provide space heating.

Peter Davey's AC Heater.

During World War II, Peter Daysh Davey, of Christchurch, New Zealand, a fighter pilot and musician, designed and built an unusual water heater. This design is not particularly well known and information is fairly thin on the ground although the basic principle and design details are known.

The device is intended to operate on New Zealand's mains supply of 220 volts 50 Hz and a requirement of the apparatus is that it resonates at that 50 Hz frequency. Resonance is a frequent requirement of free-energy systems, and the need for it is often overlooked by people who attempt to replicate free-energy devices. Properly built and tuned, this heater is said to have a COP of 20, which means that twenty times as much heat is produced as would normally be expected from that level of input power. This power gain is caused by additional energy being drawn in from the surrounding environment, and this is very important as a very large percentage of the energy used in cool climates is used for heating, so any reduction would be very welcome.

Peter was granted a New Zealand patent for his heater on 12th December 1944 but he found that opposition from the utility companies was so great that it prevented him from going into commercial production with it and although Peter kept trying for fifty years, he never succeeded.

The device is comprised of a hemispherical resonant cavity, formed by two metallic dome shapes, both of which resonate at 50 Hz. Initially, Peter used two bicycle bells and he found that when submerged in water, the device brought the water to the boil in a very short time indeed. The construction is like this:

If construction were to use two identical hemispheres, then the cavity between them would be anything but even width throughout, but the resonance would be the same. On the other hand, if you want the resonant cavity between the two hemispheres to be of constant width, then the outer hemisphere needs to be markedly larger than the inner hemisphere. The outside of both hemispheres needs to be insulated unless mounted in such a way that it is not possible to touch the hemispheres as both are attached to the mains.

In the diagram shown above, the mains live wire 6, is fed through the connecting pipe 8, and clamped to the inner hemisphere 1, by nut 3 which screws on to the threaded section of tube 8. It is important that it is the live wire which is connected to hemisphere 1. The mains neutral wire 7, is also fed through the connecting tube 8, then exits through a small hole and is then clamped on to the outside of the outer hemisphere 2, by nut 5, also on the threaded section of tube 8. The two hemispheres are held apart by a spacing washer 4, which is made from a high-temperature non-conducting plastic. As the tube 8 connects electrically and mechanically to both mains wires through the two locking nuts 3 and 5, it is essential that this tube is constructed from an electrically non-conducting material such as plastic. as the tube will be in boiling water

on a regular basis, it is also necessary that the tube material is able to handle temperatures over 100°C and so possible materials include nylon and Teflon.

The washer is a key component of the heater and its thickness is key to the efficiency of the whole device. This thickness **L**, is the tuning control for the cavity. The outer hemisphere is about 8 mm greater in diameter than the diameter of the inner hemisphere. Allowing for the thickness of the metal of the bowl, the resonant cavity will therefore be about 3 mm or one eighth of an inch.

The hemisphere **1** is also tuned to 50 Hz by grinding it carefully until it resonates freely at that frequency. Connecting a loudspeaker in series with a resistor of say, 100K ohms, will give a sound of the exact frequency with which this hemisphere needs to resonate. This tuning needs to be done with the unit fully assembled as the connections to the tube will alter the resonant frequency of the hemisphere. When this is being done, the resonance will be felt rather than heard, so hold the tube lightly so that it can resonate freely. The tuning is done by removing a small amount of metal from the face of hemisphere **1** and then testing for resonance again.

When hemisphere **1** resonates well at the mains frequency, (roughly G two octaves below middle C on a keyboard), the search for high-efficiency heating is carried out by very small adjustments of the gap **L**. The adjustment of the gap **L** is carried out by very careful grinding down of the separating washer **4** and the result is best determined by measuring the length of time needed to boil a known volume of water and the current taken to do that. Repeated tests and recorded results, shows when the best gap has been reached and the highest efficiency achieved. The heater can, of course, be used to heat any liquid, not just water.

This heater is unlike a standard kettle heating element. In the standard method, the water is not a part of the main current-carrying circuit. Instead, the mains power is applied to the heater element and the current flowing through the heater element causes it to heat up, and the heat is then conveyed to the water by conduction. In Davey's heater, on the other hand, the current flow appears to be through the water between the two hemispheres. It seems likely that the actual heating is not produced by current flow at all, but from cavitation of the water caused by the resonating of the cavity between the two hemispheres. This technique is used in small jewellery cleaners where an audio frequency is applied to a cleaning fluid in a small container.

A small amount of electrolysis will take place with the Davey heater as it in effect also forms a single parallel-connected electrolyser. The amounts should be very small as only 1.24 volts out of the 220 volts applied will be used in the electrolysis process.

An early construction of the original heater is shown in the photograph below. The coin shown in the picture is 32 mm (1.25 inch) in diameter. The heater is submerged in water when it is being used, and it brings that water to the boil exceptionally quickly. The unit was tested by New Zealand scientists who were able to vouch for its performance, but who were unable to state exactly how its operation allowed it to output such a high level of heat for such a low level of electrical input. You will notice from the photograph, how carefully the electrical connections and outer bowl are insulated.

The original prototype which Peter made was constructed from the tops of two bicycle bells, only one of which was tuned to 50 Hz. This shows that the device will definitely work if the inner hemisphere is tuned correctly.

The Series-connected Heater.

While not a free-energy device, one simple arrangement which I use myself, is an adapted halogen heater. A standard, low-cost halogen heater consists of three separate 400-watt sections with a switching arrangement which allows one, two or three sections to be powered up:

I changed the connections inside my particular heater, so that all three halogen lamps are connected in a chain. This did not involve cutting any wires or making any new connections as the wires connecting to the lamps have push-on 'spade' connectors to allow for both simple manufacturing and easy replacement of a halogen lamp. The new arrangement is like this:

This arrangement 'under-runs' the lamps as each lamp only gets one third of the voltage which it was designed for. This has the effect of increasing the working life of the lamp enormously. You would expect the heat output to be very poor, and perhaps it is. But it gives the impression of being quite effective and with all of the three sections working, it provides a gentle heat and light which seems very effective in keeping a room warm.

The Home Power, Home-Build Wind-Powered Electrical Generator.

Here is an interesting article from the Home Power web site. If you are interested in renewable power, then I strongly recommend that you visit their web site <http://www.homepower.com> and consider subscribing to their magazine as they cover many practical topics using simple wording. Here is an example of the high quality material from Home Power – a 100 watt wind generator built from scratch in just one day:

The link for this is: http://homepower.com/article/?file=HP88_pg22_Bartmann.

William McDavid's Wind-Powered Generator.

William McDavid junior remarks that a horizontal axis windmill of that type creates an area of slow-moving air behind the blades and that restricts the flow of air past the blades. A way to overcome that is to project the outgoing air in a direction which does not impede the incoming air. He shows how this can be done in his patent US Patent 6,800,955 of 5th October 2004. In this design, the wind blows into the generator housing and is deflected upwards through the fan blades of a turbine which spins an electrical generator:

One clever feature common to both of these designs is the use of a stationary circular housing with deflectors which uses the wind flow no matter what the wind direction happens to be at any given moment. Looking down from above, the housing looks like this:

This view shows two important features which enhance the performance of the device. The first is that hinged flaps allow the (horizontal) inflow of air but block the air from flowing straight out of the other side of the central section. This forces the wind to turn and flow upwards, and not only that, but this arrangement causes the air to spin, creating a miniature tornado vortex which amplifies the power of the wind as can be seen from the devastation caused by full-size tornadoes in the environment. As can be seen from the upper diagram, an upward-curving conical piece on the base of the housing assists the airflow to turn upwards as it spins. The spinning air helps to spin the generator blades faster, giving additional power.

A major additional feature is the fact that the dimension “A” is considerably less than the dimension “B” due to the reduced diameter of the housing nearer the centre. This means that the air flowing past the vanes of housing gets squeezed into a smaller space as it flows. This forces the air to speed up, causing the flow inside the central housing to be higher than the wind-speed outside and that boosts the performance of the device. This wind-powered generator looks like a straightforward project for home construction and with the air being deflected vertically, there does not appear to be any reason why several should not be located near each other. William’s full patent can be seen in the appendix of this eBook.

Frank Herbert’s Wind-Powered Generator.

As has been carefully explained by the above article, if a windmill of the blade variety is mounted low down then it is dangerous, and people on sailing boats have been killed by them. Also, if the blade arrangement is designed to operate well in low wind conditions, then it is not unusual for there to be a problem if the wind rises to gale force or higher, with some generator designs giving up and switching off entirely, even though the available free energy is at its highest level.

This design by Frank Herbert is perfectly capable of being home-built and yet it overcomes these problems as well as being a high-efficiency wind turbine. It has an outside cage which prevents human access to the moving parts inside and the ‘cage’ is not just for protection but is there to enhance the performance of the device. In passing, windmills can be used to compress air and compressed air cylinders can be used to power vehicles and/or power electrical generators during periods of heavy power requirements. The following information is from Frank Herbert’s US Patent 4,142,822 of 1979:

The vertical housing **22** shown dotted here, surrounds the vertical power take-off shaft **26**. The wind is allowed to flow through this housing at any angle, so there is no need for the housing to move. In the diagram above small discs **44** are shown at each end of the vertical shaft. These discs have arms **42** extending outwards to support a series of vertical vanes or pressure surfaces **24**. For clarity, just one vane is shown through there will actually be many of these (rather like the cutting blades on a cylinder lawnmower). In reality, there will be no arms on the discs **42** as it is much easier just to have a full-width solid disc supporting the vanes.

The outer housing has a series of vertical slats which are angled to direct the incoming wind on to the vanes at the best possible angle:

This top view of part of the device, shows the main mounting shaft **26** on which the top and bottom rotor discs are mounted. The red dots show the pivot points where the vanes **24** can turn to take the greatest advantage of the wind pressure. The incoming wind **36**, is deflected by the slats of the housing **32**, to give it

a good angle when flowing through the device as well as keeping humans away from the spinning mechanism. As the vanes and slats are located all the way around shaft **26**, sudden changes in wind direction and/or wind strength have no particular effect on this design as it operates with wind coming from any direction and no physical movement of any part of the device is needed for a change in wind direction.

The vanes can have various different profiles and still work well. The shape shown above is the shape of an aircraft wing, where a force acting towards the curved surface is generated when air flows around the shape. This is not a particularly difficult shape to construct and it is very effective in an airflow (which is why it is used to lift aircraft off the ground). There can be any convenient number of vanes and a device built as shown above should be very effective..

As the overall efficiency is improved if there is no turbulence inside the device, Frank has found a method of minimising this. For this, he uses a mechanism which can alter the shape of the vanes when the windspeed gets high. The higher windspeed whirls the vanes around faster, causing higher 'centrifugal' forces on the vanes which Frank uses as follows. Weight **54** gets pushed across by the spin rate of the rotor.

This pushes against the spring **56**, compressing it. The triangle link **59** moves upwards, pivoting at points **59a** and **59c**, and raising section **50** of the vane. This changes the shape of the vane as shown here:

The result of this changed shape is to reduce turbulence inside the device and raise the overall efficiency.

The Mead and Holmes Power System.

The US patent 4,229,661 dated 1980 from Claude Mead and William Holmes is entitled "Power Plant for Camping Trailer" proposes the use of a wind power generator to store compressed air for later use in providing household electrical current, and simultaneously charge batteries which can be used to drive the compressor in periods of very high electrical demand. There is also an option for a rapid system charge if AC mains power becomes available:

Solar Ovens.

The Solar Funnel Cooker

How to Make and Use The Brigham Young University Solar Cooker/Cooler

by Professor of Physics at Brigham Young University (BYU), with Colter Paulson, Jason Chesley, Jacob Fugal, Derek Hullinger, Jamie Winterton, Jeannette Lawler, and Seth, David, Nathan, and Danelle Jones.

Introduction

A few years ago, I woke up to the fact that half of the people in the world must burn wood or dried dung in order to cook their food. It came as quite a shock to me, especially as I learned of the illnesses caused by breathing smoke day in and day out, and the environmental impacts of deforestation - not to mention the time spent by people (mostly women) gathering sticks and dung to cook their food. And yet, many of these billions of people live near the equator, where sunshine is abundant and free. So.....

As a University Professor of Physics with a background in energy usage, I set out to develop a means of cooking food and sterilising water using the energy freely available from the sun. First, I looked at

existing methods.

The parabolic cooker involves a reflective dish which concentrates sunlight to a point where the food is cooked. This approach is very dangerous since the sun's energy is focused to a point which is very hot, but which cannot be seen. (Brigham Young University students and I built one which will set paper on fire in about 3 seconds!). I learned that an altruistic group had offered reflecting parabolas to the people living at the Altiplano in Bolivia. But more than once these parabolas had been stored next to a shed -- and the passing sun set the sheds on fire! The people did not want these dangerous, expensive devices, even though the Altiplano region has been stripped of fuel wood.

The box cooker: Is basically an insulated box with a glass or plastic lid, often with a reflecting lid to direct sunlight into the box. Light enters through the top glass (or plastic), to slowly heat up the box. The problems with this design are that energy enters only through the top, while heat is escaping through all of the other sides, which have a tendency to draw heat away from the food. When the box is opened to put food in or take it out, some of the heat escapes and is lost. Also, effective box cookers tend to be more complicated to build than the funnel cooker.

While studying this problem, I thought again and again of the great need for a safe, inexpensive yet effective solar cooker. It finally came to me at Christmastime a few years ago, a sort of hybrid between the parabola and the box cooker. It looks like a large, deep funnel, and incorporates what I believe are the best features of both the parabolic cooker and the box cooker.

The first reflector was made at my home out of aluminium foil glued on to cardboard, then this was curved to form a reflective funnel. My children and I figured out a way to make a large cardboard funnel easily. (I'll tell you exactly how to do this later on.)

The Solar Funnel Cooker is safe and low cost, easy to make, yet very effective in capturing the sun's energy for cooking and pasteurising water -> Eureka!

Later, I did extensive tests with students (including reflectivity tests) and found that aluminised Mylar was good too, but relatively expensive and rather hard to come by in large sheets. Besides, cardboard is found throughout the world and is inexpensive, and aluminium foil is also easy to come by. Also, individuals can make their own solar cookers easily, or start a cottage-industry to manufacture them for others.

Prototypes of the Solar Funnel Cooker were tested in Bolivia, and outperformed an expensive solar box cooker and a "Solar Coolkit" while costing much less than either. Brigham Young University submitted a patent application, mainly to insure that no company would prevent wide distribution of the Solar Funnel Cooker. Brigham Young University makes no profit from the invention. (I later learned that a few people had had a similar idea, but with methods differing from those developed and shown here). So now I'm trying to get the word out so that the invention can be used to capture the free energy coming from the sun - for camping and for emergencies, yes, but also for every day cooking where electricity is not available and where even fuel wood is getting scarce.

How it Works

The reflector is shaped like a giant funnel, and lined with aluminium foil. (Easy to follow instructions will be given soon). This funnel is rather like the parabolic cooker, except that the sunlight is concentrated along a line (not a point) at the bottom of the funnel. You can put your hand up the bottom of the funnel and feel the sun's heat, but it will not burn you.

Next, we paint a jar black on the outside, to collect heat, and place this at the bottom of the funnel. Or a black pot with a lid can be used. The black vessel gets hot, quickly, but not quite hot enough to cook with. We need some way to build up the heat without letting the outside air cool it. So, I put a cheap plastic bag around the jar -- and, the solar funnel cooker was born! The plastic bag, available in grocery stores as a "poultry bag", replaces the cumbersome and expensive box and glass lid of solar box ovens. You can use the plastic bags used in American stores to put groceries in, as long as they let a lot of sunlight pass. (Dark- coloured bags will not do).

I recently tested a bag used for fruits and vegetables, nearly transparent and available free at American grocery stores, that works great. This is stamped "HDPE" for high-density polyethylene on the bag (ordinary polyethylene melts too easily). A block of wood is placed under the jar to help hold the heat in. (Any insulator, such as a hot pad or rope or even sticks, will also work).

A friend of mine who is also a Physics Professor did not believe I could actually boil water with the thing. So I showed him that with this new "solar funnel cooker" I was able to boil water in Utah in the middle of winter! I laid the funnel on its side since it was winter and pointed a large funnel towards the sun to the south. I also had to suspend the black cooking vessel -- rather than placing it on a wooden block. This allows the weaker sun rays to strike the entire surface of the vessel.

Of course, the Solar Funnel works much better outside of winter days, that is, when the UV index is 7 or greater. Most other solar cookers will not cook in the winter in northern areas (or south of about 35 degrees, either).

I thought that a pressure cooker would be great. But the prices in stores were way too high for me. Wait, how about a canning jar? These little beauties are designed to relieve pressure through the lid -- a nice pressure cooker. And cooking time is cut in half for each 10°C we raise the temperature (Professor Lee Hansen, private communication). I used one of my wife's wide-mouth canning jars, spray-painted (flat) black on the outside, and it worked great. Food cooks faster when you use a simple canning jar as a pressure cooker. However, you can also put a black pot in the plastic bag instead if you want. But don't use a sealed container with no pressure release like a mayonnaise jar -- it can break as the steam builds up (I've done it)!

How to Build Your Own Solar Funnel Cooker

What You will Need for the Funnel Cooker:

A piece of flat cardboard, about 2 feet wide by 4 feet long. (The length should be just twice the width. The bigger, the better).

Ordinary aluminium foil.

A glue such as white glue (like Elmer's glue), and water to mix with it 50-50. Also, a brush to apply the glue to the cardboard (or a cloth or paper towel will do). Or, some may wish to use a cheap "spray adhesive" available in spray cans. You can also use flour paste.

Three wire brads - or small nuts and bolts, or string to hold the funnel together.

For a cooking vessel, I recommend a canning jar ("Ball" wide-mouth quart jars work fine for me; the rubber ring on the lid is less likely to melt than for other jars I've found. A two-quart canning jar is available and works fine for larger quantities of food, although the cooking is somewhat slower).

The cooking jar (or vessel) should be spray-painted black on the outside. I find that a cheap flat-black spray paint works just fine. Scrape off a vertical stripe so that you have a clear glass "window" to look into the vessel, to check the food or water for boiling.

A block of wood is used as an insulator under the jar. I use a piece of 2" x 4" board which is cut into a square nominally 4" x 4" by about 2" thick. (100 mm square x 50 mm thick). One square piece of wood makes a great insulator.

A plastic bag is used to go around the cooking-jar and block of wood, to provide a green-house effect. Suggestions:

- Reynolds™ Oven Bag, Regular Size works great: transparent and won't melt. (Cost about 25 cents each in U.S. grocery stores.)
- Any nearly-transparent HDPE bag (High-density Polyethylene). Look for "HDPE" stamped on the bag. I've tested HDPE bags which I picked up for free at my grocery store, used for holding vegetables and fruits. These are thin, but very inexpensive. Tested side-by-side with an oven bag in two solar funnels, the HDPE bag worked just as well! **Caution:** we have found that some HDPE bags will melt should they contact the hot cooking vessel. For this reason, we recommend using the oven-safe plastic bag wherever possible.
- An idea attributed to Roger Bernard and applied now to the BYU Funnel Cooker: place a pot (having a blackened bottom and sides) in a glass bowl, and cover with a lid. Try for a tight fit around the bottom to keep hot air trapped inside. The metal pot or bowl should be supported around the rim only, with an air space all around the bottom (where the sunlight strikes it). Put a blackened lid on top of the pot. Then simply place this pot-in-bowl down in the bottom of the funnel - no plastic bag is needed! This clever method also allows the cook to simply remove the lid to check the food and to stir. I like this idea - it makes the solar cooker a lot like cooking over a fire. See Photographs for further details.

Construction Steps

Cut a Half-circle out of the Cardboard

Cut a half circle out of the cardboard, along the bottom as shown below. When the funnel is formed, this becomes a full-circle and should be wide enough to go around your cooking pot. So for a 7" diameter cooking pot, the radius of the half-circle is 7". For a quart canning jar such as I use, I cut a 5" radius half-circle out of the cardboard.

Form the Funnel

To form the funnel, you will bring side A towards side B, as shown in the figure. The aluminium foil must go on the **INSIDE** of the funnel. Do this slowly, helping the cardboard to the shape of a funnel by using one hand to form creases that radiate out from the half-circle. Work your way around the funnel, bending it in stages to form the funnel shape, until the two sides overlap and the half-circle forms a complete circle. The aluminium foil will go on the **INSIDE** of funnel. Open the funnel and lay it flat, "inside up", in preparation for the next step.

Glue Foil to Cardboard

Apply glue or adhesive to the top (inner) surface of the cardboard, then quickly apply the aluminium foil on top of the glue, to affix the foil to the cardboard. Make sure the shiniest side of the foil is on top, since this becomes your reflective surface in the Funnel. I like to put just enough glue for one width of foil, so that the glue stays moist while the foil is applied. I also overlap strips of foil by about 1" (or 2 cm). Try to smooth out the aluminium foil as much as you reasonably can, but small wrinkles won't make much difference. If cardboard is not available, one can simply dig a funnel-shaped hole in the ground and line it with a reflector, to make a fixed solar cooker for use at mid-day.

Join side A to side B to keep the funnel together.

The easiest way to do this is to punch three holes in the cardboard that line up on side A and side B (see figure). Then put a metal brad through each hole and fasten by pulling apart the metal tines. Or you can use a nut-and-bolt to secure the two sides (A & B) together.

Be creative here with what you have available. For example, by putting two holes about a thumb-width apart, you can put a string, twine, small rope, wire or twist-tie in one hole and out the other, and tie together.

When A and B are connected together, you will have a "funnel with two wings". The wings could be cut off, but these help to gather more sunlight, so I leave them on.

Tape or glue a piece of aluminium foil across the hole at the bottom of the funnel, with shiny side in.

This completes assembly of your solar funnel cooker.

For stability, place the funnel inside a cardboard or other box to provide support. For long-term applications, one may wish to dig a hole in the ground to hold the Funnel against strong winds.

Final Steps

At this stage, you are ready to put food items or water into the cooking vessel or jar, and put the lid on securely. (See instructions on food cooking times, to follow).

Place a wooden block in the **INSIDE** bottom of the cooking bag. I use a piece of 2" x 4" board which is cut into a square nominally 4" x 4" by 2" thick. Then place the cooking vessel containing the food or water on top of the wooden block, inside the bag.

Next, gather the top of the bag in your fingers and **blow air into the bag, to inflate it**. This will form a small "greenhouse" around the cooking vessel, to trap much of the heat inside. Close off the bag with a tight twist tie or wire. Important: the bag should not touch the sides or lid of the cooking vessel. The bag may be called a "convection shield," slowing convection-cooling due to air currents.

Place the entire bag and its contents inside the funnel near the bottom as shown in the Photographs.

Place the Solar Funnel Cooker so that it Faces the Sun

Remember: Sunlight can hurt the eyes: so please wear sunglasses when using a Solar Cooker! The Funnel Cooker is designed so that the hot region is deep down inside the funnel, out of harm's way.

Put the Solar Funnel Cooker in the sun pointing towards the sun, so that it captures as much sunlight as possible. The design of the funnel allows it to collect solar energy for about an hour without needing to be re-positioned. For longer cooking times, readjust the position of the funnel to follow the sun's path.

In the Northern Hemisphere, it helps to put the Solar Funnel Cooker in front of a south-facing wall or window as this reflects additional sunlight into the funnel. A reflective wall is most important in locations farther from the equator and in winter. In the Southern Hemisphere, put the Solar Funnel Cooker in front of a North-facing wall or window to reflect additional sunlight into your cooker.

After Cooking

Remember that the cooking vessel will be very hot: so use cooking pads or gloves when handling it! If you are heating water in a canning jar, you may notice that the water is boiling when the lid is first removed - it gets very hot!

Open the plastic cooking bag by removing the twist-tie. Using gloves or a thick cloth, lift the vessel out of the bag and place it on the ground or table. Carefully open the vessel and check the food, to make sure it has finished cooking. Let the hot food cool before eating.

Helpful Hints

Avoid leaving fingerprints and smudges on the inside surface of the cooker. Keep the inner surface clean and shiny by wiping occasionally with a wet towel. This will keep the Solar Funnel Cooker working at its best.

If your funnel gets out-of-round, it can be put back into a circular shape by attaching a rope or string between opposite sides which need to be brought closer together.

For long-term applications, a hole in the ground will hold the Funnel Cooker securely against winds. Bring the funnel inside or cover it during rain storms.

The lids can be used over and over. We have had some trouble with the rubber on some new canning-jar lids becoming soft and "sticky." "Ball canning lids" do not usually have this problem. Running new lids through very hot water before the first use seems to help. The lids can be used over and over if they are not bent too badly when opened (pry off lid carefully).

The jar can be suspended near the bottom of the funnel using fishing line or string (etc.), instead of placing the jar on a block of wood. A plastic bag is placed around the jar with air puffed inside, as

usual, to trap the heat. The suspension method allows sunlight to strike all surfaces of the jar, all around, so that heats faster and more evenly. This suspension method is crucial for use in winter months.

Adjust the funnel to put as much sunlight onto the cooking jar as possible. Look at the jar to check where the sunlight is hitting, and to be sure the bottom is not in the shadows. For long cooking times (over about an hour), readjust the position of the funnel to follow the sun's path. During winter months, when the sun is low on the horizon (e.g., in North America), it is helpful to lay the funnel on its side, facing the sun.

Tests in Utah

I have personally used the Solar Funnel Cooker to cook lunches over many weeks. My favourite foods to cook are potatoes (cut into logs or slices) and carrot slices. Vegetables cook slowly in their own juices and taste delicious. I also make rice, melted cheese sandwiches, and even bread in the Solar Funnel Cooker. I usually put the food out around 11:30 and let it cook until 12:45 or 1 pm, just to be sure that it has time to cook. I've never had any food burn in this cooker.

I have also cooked food in the mountains, at an altitude of around 8,300 feet. If anything, the food cooked faster there - the sunlight passes through less atmosphere at high altitudes.

I find that people are surprised that the sun alone can actually cook food. And they are further pleasantly surprised at the rich flavours in the foods which cook slowly in the sun. This inexpensive device does it!

Students at Brigham Young University have performed numerous tests on the Solar Funnel Cooker along with other cookers. We have consistently found much faster cooking using the Solar Funnel Cooker. The efficiency/cost ratio is higher than any other solar cooking device we have found to date. Mr. Hullinger also performed studies of transmissivity, reflectivity and absorptivity of alternate materials which could be used in the Solar Funnel Cooker. While there are better materials, such as solar-selective absorbers, our goal has been to keep the cost of the Solar Cooker as low as possible, while maintaining safety as a first priority.

Tests in Bolivia

The BYU Benson Institute organised tests between the Solar Funnel Cooker and the "old-fashioned" solar box oven. The solar box oven cost about \$70 and was made mostly of cardboard. It took nearly two hours just to reach water pasteurisation temperature. The Bolivian report notes that "food gets cold every time the pots are taken from and into the oven." The solar box oven failed even to cook boiled eggs. (More expensive box cookers would hopefully work better.)

An aluminised-mylar Solar Funnel Cooker was also tested in Bolivia, during the Bolivian winter. Water pasteurisation temperature was reached in 50 minutes, boiled eggs cooked in 70 minutes, and rice cooked in 75 minutes. The Bolivian people were pleased by the performance. So were we! (La Paz, Bolivia, August, 1996).

I also donated two dozen solar funnel cookers for people in Guatemala. These were taken there by a group of doctors going there for humanitarian service. The people there also liked the idea of cooking with the sun's free energy. For an aluminised-Mylar Solar Funnel Cooker kit, please contact CRM (licensed manufacturer) at +1 (801) 292-9210.

Water and Milk Pasteurisation

Contaminated drinking water or milk kills thousands of people each day, especially children. The World Health Organisation reports that 80% of illnesses in the world are spread through contaminated water. Studies show that heating water to about 65° - 70° C (150° F) is sufficient to kill coliform bacteria, rotaviruses, enteroviruses and even Giardia. This is called pasteurisation.

Pasteurisation depends on how hot and how long water is heated. But how do you know if the water got hot enough? You could use a thermometer, but this would add to the cost, of course. When steam leaves the canning jar (with lid on tight) and forms "dew" on the inside of the cooking bag, then the water is probably pasteurised to drink. (The goal is to heat to 160° Fahrenheit for at least six minutes.) With a stripe of black paint scraped off the jar, one can look through the bag and into the jar and see when the water is boiling - then it is safe for sure.

Think of all the lives that can be saved simply by pasteurising water using a simple Solar Cooker!

Safety

Safety was my first concern in designing the Solar Funnel Cooker, then came low cost and effectiveness. But any time you have heat you need to take some precautions.

- The cooking vessel (jar) is going to get hot, otherwise the food inside it won't cook. Let the jar cool a bit before opening. Handle only with gloves or tongs.
- Always wear dark glasses to protect from the sun's rays. We naturally squint, but sunglasses are important.
- Keep the plastic bag away from children and away from nose and mouth to avoid any possibility of suffocation.

Cooking with the Solar Funnel Cooker

What do you cook in a crock pot or moderate-temperature oven? The same foods will cook about the same in the Solar Funnel Cooker - without burning. The charts below give approximate summer cooking times.

The solar cooker works best when the UV index is 7 or higher (Sun high overhead, few clouds).

Cooking times are approximate. Increase cooking times for partly-cloudy days, sun not overhead (e.g., wintertime) or for more than about 3 cups of food in the cooking jar.

Stirring is not necessary for most foods. Food generally will not burn in the solar cooker.

Vegetables (Potatoes, carrots, squash, beets, asparagus, etc.)

Preparation: No need to add water if fresh. Cut into slices or "logs" to ensure uniform cooking. Corn will cook fine with or without the cob.

Cooking Time: About 1.5 hours

Cereals and Grains (Rice, wheat, barley, oats, millet, etc.)

Preparation: Mix 2 parts water to every 1 part grain. Amount may vary according to individual taste. Let soak for a few hours for faster cooking. To ensure uniform cooking, shake jar after 50 minutes.

CAUTION: Jar will be hot. Use gloves or cooking pads.

Cooking Time: 1.5-2 hours

Pasta and Dehydrated Soups

Preparation: First heat water to near boiling (50-70 minutes). Then add the pasta or soup mix. Stir or shake, and cook 15 additional minutes.

Cooking Time: 65-85 minutes

Beans

Preparation: Let tough or dry beans soak overnight. Place in cooking jar with water.

Cooking Time: 2-3 hours

Eggs

Preparation: No need to add water. **Note:** If cooked too long, egg whites may darken, but taste remains the same.

Cooking Time: 1-1.5 hours, depending on desired yolk firmness.

Meats (Chicken, beef, and fish)

Preparation: No need to add water. Longer cooking makes the meat more tender.

Cooking Time: Chicken: 1.5 hours cut up or 2.5 hours whole; Beef: 1.5 hours cut up or 2.5-3 hours for larger cuts; Fish: 1-1.5 hours

Baking

Preparation: Times vary based on amount of dough.

Cooking Times: Breads: 1-1.5 hours; Biscuits: 1-1.5 hours; Cookies: 1 hour

Roasted Nuts (Peanuts, almonds, pumpkin seed, etc.)

Preparation: Place in jar. A little vegetable oil may be added if desired.

Cooking Time: About 1.5 hours

MRE's and pre-packaged foods

Preparation: For foods in dark containers, simply place the container in the cooking bag in place of the black cooking jar.

Cooking Times: Cooking time varies with the amount of food and darkness of package.

How to Use the Solar Funnel as a Refrigerator/Cooler

A university student (Jamie Winterton) and I were the first to demonstrate that the Brigham Young University Solar Funnel Cooker can be used - at night - as a refrigerator. Here is how this is done:

The Solar Funnel Cooker is set-up just as you would during sun-light hours, with two exceptions:

1. The funnel is directed at the dark night sky. It should not "see" any buildings or even trees. (The thermal radiation from walls, trees, or even clouds will diminish the cooling effect.)
2. It helps to place 2 (two) bags around the jar instead of just one, with air spaces between the bags and between the inner bag and the jar. HDPE and ordinary polyethylene bags work well, since polyethylene is nearly transparent to infrared radiation, allowing it to escape into the "heat sink" of the dark sky.

During the day, the sun's rays are reflected on to the cooking vessel which becomes hot quickly. At night, heat from the vessel is radiated *outward*, towards empty space, which is very cold indeed (a "heat sink"). As a result, the cooking vessel now becomes a small refrigerator. We routinely achieve cooling of about 20° F (10° C) below ambient air temperature using this remarkably simple scheme.

In September 1999, we placed two funnels out in the evening, with double-bagged jars inside. One jar was on a block of wood and the other was suspended in the funnel using fishing line. The temperature that evening (in Provo, Utah) was 78° F (25.5° C). Using a Radio Shack indoor/outdoor thermometer, a BYU student (Colter Paulson) measured the temperature inside the funnel and outside in the open air. He found that the temperature of the air inside the funnel dropped quickly by about 15° F (8° C), as its heat was radiated upwards in the clear sky. That night, the minimum outdoor air temperature measured was 47.5° F (8.6° C) - but the water in both jars had ICE. I invite others to try this, and please let me know if you get ice at 55 or even 60 degrees outside air temperature (minimum at night). A black PVC container may work even better than a black-painted jar, since PVC is a good infrared radiator - these matters are still being studied.

I would like to see the "Funnel Refrigerator" tried in desert climates, especially where freezing temperatures are rarely reached. It should be possible in this way to cheaply make ice for Hutus in Rwanda and for aborigines in Australia, without using any electricity or other modern "tricks." We are in effect bringing some of the cold of space to a little corner on earth. Please let me know how this works for you.

Conclusion: Why We Need Solar Cookers

The BYU Funnel Cooker/Cooler can:

- Cook food without the need for electricity or wood or petroleum or other fuels.
- Pasteurise water for safe drinking, preventing many diseases.
- Save trees and other resources.
- Avoid air pollution and breathing smoke while cooking.
- Use the sun's free energy. A renewable energy source.
- Cook food with little or no stirring, without burning.
- Kill insects in grains.
- Dehydrate fruits, etc.
- Serve as a refrigerator at night, to cool even freeze water.

(Try that without electricity or fuels!)

The burden for gathering the fuel wood and cooking falls mainly on women and children. Joseph Kiai reports :

From Dadaab, Kenya: "Women who can't afford to buy wood start at 4 am to go collecting and return about noon... They do this twice a week to get fuel for cooking... The rapes are averaging one per week."

From Belize: "Many times the women have to go into the forest dragging their small children when they go to look for wood. It is a special hardship for pregnant and nursing mothers to chop and drag trees back to the village... they are exposed to venomous snakes and clouds of mosquitoes."

And the forests are dwindling in many areas. Edwin Dobbs noted in *Audubon Magazine*, Nov. 1992, "The world can choose sunlight or further deforestation, solar cooking or widespread starvation..."

Americans should be prepared for emergencies, incident to power failures. A Mormon pioneer noted in her journal: "We were now following in their trail travelling up the Platte River. Timber was sometimes very scarce and hard to get. We managed to do our cooking with what little we could gather up..." (Eliza R. Snow) Now there's someone who needed a light-weight Solar Cooker!

Here's another reason to use a solar cooker. Many people in developing countries look to see what's being done in America. I'm told that if Americans are using something, then they will want to try it, too. The more people there are cooking with the sun, the more others will want to join in. A good way to

spread this technology is to encourage small local industries or families to make these simple yet reliable solar cookers for others at low cost. I've used this cooker for three summers and I enjoy it. Cooking and making ice with the funnel cooker/cooler will permit a significant change in lifestyle. If you think about it, this could help a lot of people. The BYU Solar Funnel Cooker uses the glorious sunshine -- and the energy of the sun is a free gift from God for all to use!

Answers to commonly-asked questions

Will the cooker work in winter (in the United States)?

As the sun moves closer to the southern horizon in the winter, the solar cooker is naturally less effective. A good measure of the solar intensity is the "UV index" which is often reported with the weather. When the ultraviolet or UV index is 7 or above – common in summer months – the solar cooker works very well. In Salt Lake City in October, the UV index was reported to be 3.5 on a sunny day. We were able to boil water in the Solar Funnel Cooker during this time, but we had to suspend the black jar in the funnel so that sunlight struck all sides. (We ran a fishing line under the screw-on lid, and looped the fishing line over a rod above the funnel. As usual, a plastic bag was placed around the jar, and this was closed at the top to let the fishing line out for suspending the jar.)

The solar "minimum" for the northern hemisphere occurs on winter solstice, about December 21st each year. The solar "maximum" occurs six months later, June 21st. Solar cooking works best from about 20th March to 1st October in the north. If people try to cook with the sun for the first time outside of this time window, they should not be discouraged. Try again when the sun is more directly overhead. One may also suspend the jar in the funnel, which will make cooking faster any time of the year.

It is interesting to note that most developing countries are located near the equator where the sun is nearly directly overhead all the time. Solar Cookers will then serve year-round, as long as the sun is shining, for these fortunate people. They may be the first to apply fusion energy (of the sun) on a large scale. They may also accomplish this without the expensive infrastructure of electrical power grids that we take for granted in America.

How do you cook bread in a jar?

I have cooked bread by simply putting dough in the bottom of the jar and placing it in the funnel in the usual way. Rising and baking took place inside the jar in about an hour (during summer). One should put vegetable oil inside the jar before cooking to make removal of the bread easier. I would also suggest that using a 2-quart wide-mouth canning jar instead of a 1-quart jar would make baking a loaf of bread easier.

What is the optimum "opening angle" for the funnel cooker?

A graduate student at Brigham Young University did a calculus calculation to assess the best shape or opening angle for the Solar Funnel. Jeannette Lawler assumed that the best operation would occur when the sun's rays bounced no more than once before hitting the cooking jar, while keeping the opening angle as large as possible to admit more sunlight. (Some sunlight is lost each time the light reflects from the shiny surface. If the sunlight misses on the first bounce, it can bounce again and again until being absorbed by the black bottle). She set up an approximate equation for this situation, took the calculus derivative with respect to the opening angle and set the derivative equal to zero. Optimising in this way, she found that the optimum opening angle is about 45 degrees, when the funnel is pointed directly towards the sun.

But we don't want to have to "track the sun" by turning the funnel every few minutes. The sun moves (apparently) 360 degrees in 24 hours, or about 15 degrees per hour. So we finally chose a 60-degree opening angle so that the cooker is effective for about 1.2 hours. This turned out to be long enough to cook most vegetables, breads, boil water, etc. with the Solar Funnel Cooker. We also used a laser pointer to simulate sun rays entering the funnel at different angles, and found that the 60-degree cone was quite effective in concentrating the rays at the bottom of the funnel where the cooking jar sits.

For questions regarding the complete Solar Funnel Cooker kit using aluminised Mylar and a jar for the cooking vessel, please contact CRM at +1 (801) 292-9210.

Tests of the Solar Funnel and Bowl Cookers in 2001

Introduction

With an increase in population and a decrease in available fuels such as wood and coal in developing countries, the need for alternative cooking methods has increased. Solar cookers are an alternative to conventional methods such as wood-fires and coal-fires. They provide usable heat for cooking and pasteurising water, without the harmful side effects such as smoke inhalation that non-renewable sources create. In many countries such as Haiti, Bolivia and Kenya, the need for cheap, effective, and safe cooking methods has increased due to poverty and deforestation. Solar cookers are ideal because they rely on the sun's free energy which is abundant in many of the world's poorest countries. Though there are good designs, more testing and improvement is desirable.

There are three areas of comparison that were focused on during the course of the study. The first area of comparison is in the reflective material used. The original material is a mirror-finished aluminium Mylar. Due to the mirror finish, the reflection light is very bright and can be difficult to work over when cooking. An alternative material is a matt-finish Mylar. This material diffuses the sunlight and is not as harsh on the eyes as is the mirrored finish.

The second area of concentration is on the method of containing the air that surrounds the cooker so that the cooker is kept from being cooled by convection currents. A common method is to use a clear plastic oven-safe bag around the cooking vessel. However, this method is rather tedious and awkward to use, and such bags are rarely available in developing countries. Another technique is to use a disk or window make out of a clear plastic or glass. This makes the cooker easier to use.

The third main area of focus is in the cooking containers used. The present cooking vessel for the Solar Funnel Cooker is a black-painted canning jar. This method is also tedious and awkward. The canning jars can be hard to clean, and they can break. Design changes are tested that would allow people to use their own cookware. This too would make the cooker more convenient to use.

The fourth area of testing pitted the wooden block support which we have been using for years against a rabbit-wire support. A rabbit-wire cylinder holds the cooking vessel up off the bottom of the cooker, and allows sunlight to strike essentially all surfaces of the cooking vessel, including the bottom.

The effectiveness of these methods is tested and compared both qualitatively and quantitatively. In addition to acquiring temperature-rise versus time data, we also cooked numerous meals in the solar cookers so as to get hands-on experience with cooking. Several students participated in these cooking tests.

Cooker Designs:

Several solar cooker designs were used during these tests. The Solar Funnel Cooker was the main cooker tested. A Solar CookKit and a bowl-shaped variation of the Solar Funnel Cooker were also tested. Most experiments were comparative tests between the various designs, and the cooker set-up was varied from test to test. The basic design of the Solar Funnel Cooker is a funnel-shaped aluminium Mylar collector. A highly reflective material is necessary to collect and concentrate the sun's rays. The funnel walls are at a 60 degree angle (with respect to the horizontal) since this collects sunlight for a two hour time period without requiring re-orientation to follow the sun. Due to the way the Mylar sheets are cut and folded, a pair of wings

on opposite ends of the funnel is formed. The wings increase the collector size and create an elliptical shape at top. At the tips of the wings, the cooker stands about 20 inches high and has a diameter of about 28 inches. At the top, along the minor axis of the elliptical funnel, the cooker stands about 15 inches high, and has a diameter of about 20 inches. Since the Aluminium Mylar does not support itself well, a nine inch diameter by five inch high bucket is used to support the funnel.

The cooking container primarily tested is a glass canning jar that has been painted flat black. The black paint allows the jar to absorb the sun's rays. The canning jar works well due to the added pressure-cooker effect caused by the rubber ring on the inside of the lid. A black-enamel pot and a black-painted stainless steel canister were also used. We found immediately that raising the vessel off the bottom of the cooker using a rabbit-wire stand provided more rapid and even heating than the wooden block used previously. Placing the jar or pot on a wire stand allows as much reflected light onto the cooking vessel as possible. This allows even the bottom of the cooking container to absorb thermal energy that is reflected off the lower portion of the funnel.

Two methods of closing the cookers off from convection currents were used. It is important to keep the air that surrounds the container from circulating, thus keeping the cooking container from being cooled by convection currents or breezes. This first method used was to enclose the cooking vessel and wire stand in a clear plastic bag, such as a heat resistant Reynolds Oven Bag. It is important to make sure that the bag is not touching the cooking vessel, so once the vessel is placed into the clear bag, air is blown into the bag and the bag is tied off. This is the most common method used for solar panel cookers, such as the Solar CookIt, because of the bags' ability to withstand the temperatures attained in these types of cookers. But these bags tear rather easily and they are not readily available in developing countries and must be imported.

The second method of closing off the cooking vessel from convection currents, designed by Dr. Jones, is to place a clear plastic disk down into the funnel above the cooking vessel. The funnel used in the test was a conventional-shaped funnel that was constructed out of thin sheet metal and aluminium-foil lined for better reflectivity. The diameter of this funnel is about 30 inches at the top, and it stands about 16 inches high. The walls also form about a 60 degree angle with respect to the horizontal. This funnel was designed to hold a larger cooking container such as a pot. The diameter of the plastic disk is large enough that the disk does not touch the top of the container. For the experiments that tested this method, a one-sixteenth inch (1.6 mm) thick Lexan disk was used.

Data Collection

To collect the temperatures as a function of time, a Texas Instruments Calculator Based Laboratory (CBL) was used. This portable interface is capable of recording real-time data from multiple channels. The data were downloaded into a graphing calculator, where they can be analysed and graphed immediately. From the calculator, the data can be transferred to a computer spreadsheet such as Microsoft Excel for further analysis. Due to the nature of these experiments and the low cost to purchase the CBL, this is an ideal data collector to use. A graphing calculator was used to program the CBL and to tell it what data to collect, how many points to collect, and the time period between data points collected. Since the CBL does not have any internal programs for data collection, a program must be written into the graphing calculator. There are

ready-made programs that can be uploaded into the calculator, or a custom program can be made to fit the needs of the test. The program that the CBL used allowed multiple thermocouples to collect data simultaneously. To ensure that the thermocouples were calibrated against each other, both were run on the same constant temperature sample in very close proximity. Both temperature probes agreed to within 0.21°C of each other. For these experiments, this temperature difference was considered to be acceptable.

Procedure

Each experiment was conducted on the campus of Brigham Young University during mid-day, usually between 11:00 am and 2:00 pm to ensure that the sun was close to being directly over-head. This allowed as much sun light as possible to enter the solar collector. Each experiment included several steps, as listed below.

Before each experiment was set up, the volume of the water and the mass of the container were measured and recorded. The heat capacity of the water and the container were also found. The area of the cooker perpendicular to the sun's rays was also measured. To collect temperature data using thermocouple probes, small holes were drilled into the top of the canning jar and stainless steel canister lids. The jar and canister were both painted ultra-flat black to absorb as much of the sun's energy as possible.

On the morning of each test, the designated volume of water was measured out and poured into the cooking vessel. This volume ranged from 0.6 litre for one-quart jars, to 1.2 liters for half-gallon canning jars. For simultaneous testing, the same amount of water was poured into each container. The temperature probes were wired through the holes in the lids of the containers and secured about 13 mm into the water. For comparative tests, the probes were placed the same depth into the water to ensure that the probes did not read different measurements due to depth-related temperature differences within the containers. To enable later analysis; the time, ambient temperature, and solar irradiance were also noted and recorded. These numbers gave a reference point for each test. Each cooker that was to be tested was then completely set up. The temperature probes were secured through the lids, and the jar was placed into the clear oven bag – supported by a wire cage. Each bag was inflated so that no part of the bag touched the sides or top of the cooking container. The cord from the thermocouple to the CBL was passed through the top of the bag, and the bag was tied off with a twist-tie.

The test began once both cookers were completely ready and the CBL had been programmed. Care was taken to block the sun from radiating directly onto the cookers until both were ready to begin. This ensured that the water in both cookers started at very nearly the same temperature. Most tests were set up to collect one data point every four to five minutes, for up to two hours. This allowed the cooker temperatures to reach maxima and then remain at a nearly constant temperature. Once a test was complete, the cooker was disassembled and the data downloaded into the graphing calculator. Though the graphing calculator does allow analysis, a spread sheet such as Microsoft Excel is easier to use. Thus, the data from each test were downloaded from the calculator into Microsoft Excel. The elapsed time (in seconds) and the corresponding temperatures were listed next to each other. A graph of temperature versus time was made, with the Time being the horizontal axis for each test. For comparative tests, the Temperature versus Time data for both cookers was plotted on the same graph. As a reference, a trend-line was fitted to the linear portion of the graph, along with the linear regression and the coefficient of correlation (R²). It is important to have a coefficient of correlation close to one, as this is how close the linear regression fits the data. In a separate column, the temperatures were again listed, however only from 30°C to 70°C. The change in temperature for every ten or twelve minutes was found and logged next to the temperature column. The power output (in Watts) of each cooker could then be calculated.

To calculate the power output of the cookers for each specific test, the mass of the water and of the container were both measured. Though the thermal energy content of the container was relatively small compared to that of water (due to the large heat capacity of water), it was important to add it into the calculation. Also, since several different containers were compared, the energy content of the container was important. The power is found by:

$$Q_{(out)} = Q_{(water)} + Q_{(container)}$$

$$Q_{(out)} = (m_w c_w + m_c c_c) \Delta T$$

$$Power_{(out)} = \frac{Q_{(out)}}{\Delta t}$$

The power is found in Watts. A power output for each change in temperature for the time interval is calculated and logged next to the T column. Since there are uncertainties in all of the measurements, it is important to include the error in each power output. To do this, the error in the water's and container's measurements is taken into consideration. The error is found by:

$$\pm \Delta P = \sqrt{\left(\frac{\partial P}{\partial m_w} \Delta m_w\right)^2 + \left(\frac{\partial P}{\partial m_c} \Delta m_c\right)^2 + \left(\frac{\partial P}{\partial t} \Delta t\right)_w^2 + \left(\frac{\partial P}{\partial t} \Delta t\right)_c^2 + 2\left(\frac{\partial P}{\partial T} \Delta T\right)_w + 2\left(\frac{\partial P}{\partial T} \Delta T\right)_c}$$

Where $\pm \Delta P$ is the total error in the calculated error, Δm_w and Δm_c are the error in the mass of the water and container respectively, ΔT_p is the error in the temperature difference, and Δt is the error in the time interval.

This simplifies to:

$$\pm \Delta P = \sqrt{\left[\left(\frac{c_w \Delta T}{t} \Delta m_w\right)^2 + \left(\frac{c_c \Delta T}{t} \Delta m_c\right)^2 + \left(\frac{m_w c_w \Delta T}{t^2} \Delta t\right)^2 + \left(\frac{m_c c_c \Delta T}{t^2} \Delta t\right)^2 + 2\left(\frac{m_w c_w}{t} \Delta T_p\right)^2 + 2\left(\frac{m_c c_c}{t} \Delta T_p\right)^2}\right]}$$

The error was found only for the average change in temperature, rather than for each individual temperature measurement. Since the power output is dependant on the amount of energy coming in from the sun, the cooker efficiency is a good factor to calculate. To find the efficiency, the total amount of local solar radiation must be known. This should be given in watts per square metre, so that the input wattage can be found. To find the power coming in, the area of the cooker perpendicular to the sun's rays was multiplied by the solar radiation to give the amount of power that was being collected by the cooker. Since the Solar Funnel is able to be kept on track with the sun, and since the tests were done during mid-day, it was not necessary to calculate any angles. The efficiency is simply the power output divided by the power input. The solar radiation for each test was supplied by the Department of Physics and Astronomy weather station at Brigham Young University in Provo, UT, where the tests took place.

Results:

Matt vs. Mirror: Several tests were conducted on the matt versus mirror finishes. In each test, the matt finish outperformed the mirror finish. On 27 July, 2001, a matt funnel and a mirror funnel were simultaneously tested with 650 cc of water. The average power output for the mirror finish was $46.4 \text{ W} \pm 1.7 \text{ W}$, while the matt funnel put out an average of $59.4 \text{ W} \pm 2.1 \text{ W}$. The efficiency of the mirror funnel was 15.8%, while the matt was 20.2% efficient.

The following graph shows the temperatures reached by the matt and mirror funnels.

Channel 1 (Ch1) was the mirror finish, and channel 2 (Ch2) was the matt finish. This shows that both funnels peaked at about the same temperature: 97°C (207°F). The matt funnel peaked in about 76 minutes, whereas the mirror funnel peaked in 96 minutes, twenty minutes later. Though this perhaps a tolerable time difference for actual cooking, it is substantial. Every matt vs. mirror test performed in a similar way. These results are due to the way the matt funnel reflects the sun's rays. The mirror finish seems to focus a strip of light onto the cooking vessel more than the matt finish does. As a result, the matt finish diffuses the light more and the cooker is heated more uniformly. This is good, since the matt finish is easier to work with, delivering much less glare to the eyes.

The following graph shows the temperature rise with time for a Solar CookKit:

Comparing the two graphs above, we find that the Solar CookKit performed very well, comparable to the Funnel Cooker. We should note that in both cases, we used a canning jar (pressurised) supported by a wire stand. We found that the wire stand improves the performance of the Solar CookKit significantly and hope that this support stand will be used in countries where the Solar CookKit is in use.

In tests where the use of the clear plastic disk was tested against the oven-bag, an aluminium pot was used in the disk-set-up. In these tests, the cooker with an oven bag outperformed the cooker using a plastic disk. On 10 August, 2001, a test was run which compared the disk/pot set-up against the oven-bag/jar set-up. Both cookers follow similar heating paths with time, but the oven-bag/jar did slightly better. Due to the higher mass of the jar compared to the mass of the aluminium pot, and the much higher heat capacity of the water, the average power output for the oven-bag/jar was 39.8 ± 1.4 W, while the disk/pot put out $30.3 \text{ W} \pm 1.2$ W. The efficiency of the oven-bag/jar was 14.7% and the efficiency of the disk/pot set-up was 10.4% for this test. This is also partly due to the pressure-cooker effect that the canning jar produces. Though this is a considerable efficiency difference, the disk/pot set-up did very well in subjective tests where food was actually cooked and tasted. In all cases where the disk/pot set-up was used to cook food, the food cooked in about the same amount of time. The ease of the disk/pot set-up is also an important consideration. Overall, in tests where food was cooked, the disk/pot set-up was preferred over the oven-bag/jar set-up.

Conclusions:

As many countries are depleting their natural resources due to increased population and the resulting deforestation, methods other than burning wood are needed to cook food and pasteurise water. Solar

cookers provide a sustainable technology that relies on the sun's free energy. We report several advances to make them better. The need for cheap and effective solar cookers is very great and growing.

The Solar Funnel Cooker has been designed to meet the growing need by being inexpensive and effective. We determined that the Solar CookKit was nearly as effective when a rabbit-wire stand was used to support the cooking vessel. By collecting time vs. temperature data, quantitative analysis has been done. This analysis approach is useful for further development of the cookers.

Several areas of research were explored in 2001. Two finishes were tested for the reflector, a matt finish and a mirror finish. The benefits of the matt over the mirror finish are:

- 1) The matt finish is easier to work over because the sun's glaring reflection is diffused, and
- 2) the matt finish out-performs the mirror finish in temperature vs. time tests.

The method of closing off the cooker from convection current was tested and compared with an alternative method – a clear plastic disk. The use of a pot rather than a canning jar was also tested. Though the present oven-bag/jar method does outperform the disk/pot method, the disk/pot method is easier to use and seems to be nearly as efficient. Finally, we showed that a wire-mesh stand is a considerable improvement over the use of a wooden block or other opaque stand for the cooking vessel. We join with our fellow researchers around the world in pursuing further development of solar cookers, particularly to benefit people in developing countries.

Recent Advances in Solar Water Pasteurisation

Boiling isn't necessary to kill disease microbes

The main purpose of solar cookers is to change sunlight into heat which is then used to cook foods. We are all familiar with how successful solar cookers are at cooking and baking a wide variety of foods. In this article I want to consider using the heat in solar cookers for purposes other than cooking. My main focus will be solar water pasteurisation, which can complement solar cooking and address critical health problems in many developing countries.

The majority of diseases in developing countries today are infectious diseases caused by bacteria, viruses, and other microbes which are shed in human faeces and polluted water which people use for drinking or washing. When people drink the live microbes, they can multiply, cause disease, and be shed in faeces into water, continuing the cycle of disease transmission.

World-wide, unsafe water is a major problem. An estimated one billion people do not have access to safe water. It is estimated that diarrhoeal diseases that result from contaminated water kill about 2 million children and cause about 900 million episodes of illness each year.

Boiling contaminated water

How can infectious microbes in water be killed to make the water safe to drink? In the cities of developed countries this is often guaranteed by chlorination of water after it has been filtered. In developing countries, however, city water systems are less reliable, and water from streams, rivers and some wells may be contaminated with human faeces and pose a health threat. For the billion people who do not have safe water to drink, what recommendation do public health officials offer? The only major recommendation is to boil the water, sometimes for up to 10 minutes. It has been known since the time of Louis Pasteur 130 years ago that heat of boiling is very effective at killing all microbes which cause disease in milk and water.

If contaminated water could be made safe for drinking by boiling, why is boiling not uniformly practised? There seem to be five major reasons:

- 1) people do not believe in the germ theory of disease,
- 2) it takes too long,
- 3) boiled water tastes bad,
- 4) fuel is often limited or costly,
- 5) the heat and smoke are unpleasant.

Some examples of the cost of boiling water are worth mentioning. During the cholera outbreak in Peru, the Ministry of Health urged all residents to boil drinking water for 10 minutes. The cost of doing this would amount to 29% of the average poor household income. In Bangladesh, boiling drinking water would take 11% of the income of a family in the lowest quartile. In Jakarta, Indonesia, more than \$50 million is spent each year by households for boiling water. It is estimated that in the city of Cebu in the Philippines, population about 900,000, about half the families boil their drinking water, and the proportion is actually higher for families that obtain their water from an unreliable chlorinated piped supply. Because the quantities of fuel consumed for boiling water are so large, approximately 1 kilogram of wood to boil 1 litre of water, and because firewood, coal, and coke are often used for this purpose, an inadequate water supply system significantly contributes to deforestation, urban air pollution, and other energy-related environmental effects.

If wood, charcoal, or dung is used as fuel for boiling water, the smoke creates a health hazard, as it does all the time with cooking. It is estimated that 400 to 700 million people, mainly women, suffer health problems from this indoor air pollution. As a microbiologist, I have always been perplexed as to why boiling is recommended, when this is heat far in excess of that which is necessary to kill infectious microbes in water. I presume the reason boiling is recommended is to make sure that lethal temperatures have been reached, since unless one has a thermometer it is difficult to tell what temperature heated water has reached until a roaring boil is reached. Everyone is familiar with the process of milk pasteurisation. This is a heating process which is sufficient to kill the most heat resistant disease causing microbes in milk, such as the bacteria which cause tuberculosis, undulant fever, streptococcal infections and Salmonellosis. What temperatures are used to pasteurise milk? Most milk is pasteurised at 71.7° C (161° F) for only 15 seconds. Alternatively, 30 minutes at 62.8° C (145° F) can also pasteurise milk. Some bacteria are heat resistant and can survive pasteurisation, but these bacteria do not cause disease in people. They can, however, spoil the milk, so pasteurised milk is kept refrigerated.

There are some different disease microbes found in water, but they are not unusually heat resistant. The most common causes of water diseases, and their heat sensitivity, are presented in Table 1. The most common causes of acute diarrhoea among children in developing countries are the bacteria *Escherichia coli* and *Shigella* SD. and the Rotavirus group of viruses. These are rapidly killed at temperatures of 60° C or greater.

Solar water pasteurisation

As water heats in a solar cooker, temperatures of 56° C and above start killing disease-causing microbes. A graduate student of mine, David Ciochetti, investigated this for his master's thesis in 1983, and concluded that heating water to 66° C in a solar cooker will provide enough heat to pasteurise the water and kill all disease causing microbes. The fact that water can be made safe to drink by heating it to this lower temperature - only 66° C - instead of 100° C (boiling) presents a real opportunity for addressing contaminated water in developing countries.

Testing water for faecal contamination

How can one readily determine if the water from a well, pump, stream, etc. is safe to drink? The common procedure is to test the water for bacterial indicators of faecal pollution. There are two groups of indicators which are used. The first is the coliform bacteria which are used as indicators in developed countries where water is chlorinated. Coliform bacteria may come from faeces or from plants. Among the coliform bacteria is the second indicator, *Escherichia coli*. This bacterium is present in large numbers in human faeces (approximately 100,000,000 per gram of faeces) and that of other mammals. This is the main indicator used if water is not chlorinated. A water source containing 100 *E. coli* per 100 ccs poses a substantial risk of disease.

The standard method of testing water for the presence of coliforms and *E. coli* requires trained personnel and a good laboratory facility or field unit which are usually not present in developing countries. Thus, water supplies are almost never tested.

A new approach to testing in developing countries

In 1987, the Colilert MPM Test (CLT) was introduced as the first method which used a defined substrate technology to simultaneously detect coliforms and *E. coli*. The CLT comes as dry chemicals in test tubes containing two indicator nutrients: one for coliforms and one for *E. coli*. The CLT involves adding 10 ml of water to a tube, shaking to dissolve the chemicals, and incubating at body temperature for 24 hours. I prefer incubating tubes under my belt against my body. At night I sleep on my back and use night clothes to hold the tubes against my body.

If no coliform bacteria are present, the water will remain clear. However, if one or more coliforms are present in the water, after 24 hours their growth will metabolise ONPG and the water will change in colour from clear to yellow (resembling urine). If *E. coli* is among the coliform bacteria present, it will metabolise MUG and the tube will fluoresce blue when a battery-operated, long-wave ultraviolet light shines on it, indicating a serious health hazard. I have invited participants at solar box cooker workshops in Sierra Leone, Mali, Mauritania, and Nepal to test their home water supplies with CLT. One hundred and twenty participants brought in samples. In all four countries, whether the water was from urban or rural areas, the majority of samples contained coliforms, and at least half of these had *E. coli* present. Bacteriological testing of the ONPG and MUG positive tubes brought back from Mali and Mauritania verified the presence of coliforms/*E. coli* in approximately 95% of the samples. It is likely that soon the Colilert MPN test will be modified so that the test for *E. coli* will not require an ultraviolet light, and the tube will turn a different colour than yellow if *E. coli* is present. This will make the test less expensive and easier to widely use in developing countries to assess water sources.

Effect of safe water on diarrhoea in children

What would be the effect if contaminated water could be made safe for drinking by pasteurisation or boiling? One estimate predicts that if in the Philippines, families at present using moderately contaminated wells (100 *E. coli* per 100 ml) were able to use a high-quality water source, diarrhoea among their children would be reduced by over 30%. Thus, if water which caused a MUG (+) test were solar pasteurised so it would be clear, this would help reduce the chance of diarrhoea, especially in children.

Water pasteurisation indicator

How can one determine if heated water has reached 65°C? In 1988, Dr. Fred Barrett (USDA, retired) developed the prototype for the Water Pasteurisation Indicator (WAPI). In 1992, Dale Andreatta, a graduate engineering student at the University of California, Berkeley, developed the current WAPI. The WAPI is a polycarbonate tube, sealed at both ends, partially filled with a soybean fat which melts at 69°C

("MYVEROL" 18-06K, Eastman Kodak Co., Kingsport, TN 37662). The WAPI is placed inside a water container with the fat at the top of the tube. A washer will keep the WAPI on the bottom of the container, which heats the slowest in a solar box cooker. If heat from the water melts the fat, the fat will move to the bottom of the WAPI, indicating water has been pasteurised. If the fat is still at the top of the tube, the water has not been pasteurised.

The WAPI is reusable. After the fat cools and becomes solid on the bottom, the fish line string is pulled to the other end and the washer slides to the bottom, which places the fat at the top of the tube. Another pasteurisation indicator has been developed by Roland Saye which is based on expansion of a bi-metal disc which is housed in a plastic container. This also shows promise and is in the early testing stages. The WAPI could be useful immediately for people who currently boil water to make it safe to drink. The WAPI will indicate clearly when a safe temperature has been reached, and will save much fuel which is currently is being wasted by excessive heating.

[Editor's note: Using Beeswax & Carnauba Wax to Indicate Temperature: In SBJ #15 we discussed using beeswax, which melts at a relatively low 62° C, as an indicator of pasteurisation. We have now found that mixing a small amount of carnauba was with the beeswax (~1:5 ratio) raises the melting temperature of the beeswax to 70° - 75° C. Carnauba wax is a product of Brazil and can be bought in the US at woodworking supply stores. Further testing needs to be done to confirm that the melting point remains the same after repeated re-melting.

Different strategies for solar water pasteurisation

The solar box cooker was first used to pasteurise water. David Ciochetti built a deep-dish solar box cooker to hold several gallons of water. At this time of the year in Sacramento, three gallons could be pasteurised on our typical sunny days.

Dale Andreatta and Derek Yegian of the University of California, Berkeley, have developed creative ways to greatly increase the quantity of water which can be pasteurised, as we will hear about at this conference.

I am also excited about the possibility of pasteurising water using the simple solar panel cookers. By enclosing a dark water container in a polyester bag to create an insulating air space, and by using lots of reflectors to bounce light onto the jar, it is possible to pasteurise useful amounts of water with a simple system. It takes about four hours for me to pasteurise a gallon of water in the summer with the system I am using. Solar panel cookers open up enormous possibilities for heating water not only for pasteurisation, but also for making coffee and tea, which are quite popular in some developing countries. The heated water can also be kept hot for a long time by placing it in its bag inside an insulated box. In the insulated container I use, a gallon of 80° C water will be approximately 55° C after 14 hours. Water at a temperature of 55° C will be about 40° C after 14 hours, ideal for washing/shaving in the morning.

I will close with some advice from the most famous microbiologist, who pioneered the use of vaccinations in the 1890s: Louis Pasteur. When he was asked the secret of his success, he responded that above all else, it was persistence. I will add that you need good data to be persistent about, and we certainly have that with solar cookers; the work in Sacramento, Bolivia, Nepal, Mali, Guatemala, and wherever else the sun shines. Continued overuse of fuel-wood is non-sustainable. We need to persist until the knowledge we have spreads and becomes common knowledge world-wide.

Editor's Note: Testing Water in Developing Countries

The Colilert system makes it possible to test water without the need for a laboratory. IDEXX Laboratories, the manufacturer, recommends that you use five test tubes for each sample. Bob Metcalf explains that five tubes would comprise 50 ml, which is the minimum sample size permitted by US law. This is an unrealistically high standard by which to judge the water in developing countries where you are examining water that is already being drunk, in spite of the fact that it may be making people sick. By using a single test tube (10 ml) there is a very small chance that your sample missed the small number of bacteria that might have been present.

IDEXX Laboratories will also tell you that you need an incubator to achieve valid results. Again, Bob Metcalf tells us that all that is needed is to keep the tubes close to your body for 36 hours, since body temperature is the correct incubation temperature.

What you are actually measuring in the test is the presence of 1) coliform bacteria, and 2) E. coli, a type of coliform bacteria that is largely found in faecal matter. A positive test for coliform bacteria might be due to coliform bacteria that has washed off of plant leaves, and thus be fairly innocuous. A positive test for E. coli, however, would indicate that any bacteriological contamination was from a faecal source, which might also contain Giardia, cholera, or other serious infectious microbes.

The Solar Puddle

A new water pasteurisation technique for large amounts of water

The lack of clean drinking water is a major health problem in the developing world. To reduce this health risk ways of producing clean water at an affordable cost are needed, and people need to be educated about germs and sanitation, lest they accidentally re-contaminate their clean drinking water. Recently, several of us at the University of California at Berkeley have attacked the first of these requirements. Previous issues of this newsletter have included stories about our water pasteurisation indicator and our flow-through water pasteuriser based on a design by PAX World Service. In this article we describe a new low-cost device that pasteurises water.

For those not familiar with the pasteurisation process, if water is heated to 149° F (65° C) for about 6 minutes all the germs, viruses, and parasites that cause disease in humans are killed, including cholera and hepatitis A and B. [Ed. We have reports from the field that at 145° F (63° C) in a solar puddle, bacterial growth might actually be increased. Since this temperature is very close to the minimum pasteurisation temperature mentioned in this article, we suggest that you heat the water to a higher

temperature and perform tests before adopting a solar puddle as your method of pasteurisation]. This is similar to what is done with milk and other beverages. It is not necessary to boil the water as many people believe. Pasteurisation is not the only way to decontaminate drinking water, but pasteurisation is particularly easy to scale down so the initial cost is low.

The new device is called a solar puddle, and it is essentially a puddle in a greenhouse. One form of the solar puddle is sketched in the figure below, though many variations are possible.

One begins by digging a shallow pit about 4 inches deep. The test device was a "family-size" unit, about 3.5 feet by 3.5 feet, but the puddle could be made larger or smaller. If the puddle is made larger there is more water to pasteurise, but there is also proportionately more sunshine collected. The pit is filled with 2 to 4 inches of solid insulation. We used wadded paper, but straw, grass, leaves, or twigs could be used. This layer of insulation should be made flat, except for a low spot in one corner of the puddle.

Put a layer of clear plastic and then a layer of black plastic over the insulation with the edges of the plastic extending up and out of the pit. Two layers are used in case one develops a small leak. We used inexpensive polyethylene from a hardware store, though special UV stabilised plastic would last longer. Put in some water and flatten out the insulation so that the water depth is even to within about 0.5 inch throughout the puddle, except in the trough which should be about 1 inch deeper than the rest. Put in more water so that the average depth is 1 to 3 inches depending on how much sunshine is expected.

A pasteurisation indicator (available from Solar Cookers International at 916/455-4499) should go in this trough since this is where the coolest water will collect. Put a layer of clear plastic over the water, again with the edges extending beyond the edges of the pit. Form an insulating air gap by putting one or more spacers on top of the third layer of plastic (large wads of paper will do) and putting down a fourth layer of plastic, which must also be clear. The thickness of the air gap should be 2 inches or more. Pile dirt or rocks on the edges of the plastic sheets to hold them down. The puddle is drained by siphoning the water out, placing the siphon in the trough and holding it down by a rock or weight. If the bottom of the puddle is flat, well over 90% of the water can be siphoned out.

Once the puddle is built it would be used by adding water each day, either by folding back the top two layers of plastic in one corner and adding water by bucket, or by using a fill siphon. The fill siphon should NOT be the same siphon that is used to drain the puddle, as the fill siphon is re-contaminated each day, while the drain siphon MUST REMAIN CLEAN. Once in place the drain siphon should be left in place for the life of the puddle.

The only expensive materials used to make the puddle are a pasteurisation indicator (about \$2 for the size tested). All of these items are easily transportable, so the solar puddle might be an excellent option for a refugee camp if the expertise were available for setting them up.

Many tests were done in the spring and summer of this year in Berkeley, California. On days with good sunshine the required temperature was achieved even with 17 gallons of water (2 1/2 inch depth). About 1 gallon is the minimum daily requirement per person, for drinking, brushing one's teeth, and dish washing. With thinner water layers higher temperatures can be reached. With 6 gallons (1 inch depth) 176° F was achieved on one day.

The device seems to work even under conditions that are not ideal. Condensation in the top layer of plastic doesn't seem to be a problem, though if one gets a lot of condensation the top layer should be

pulled back to let the condensation evaporate. Small holes in the top layers don't make much difference. The device works in wind, or if the bottom insulation is damp. Water temperature is uniform throughout the puddle to within 2° F.

After some months the top plastic layers weaken under the combined effects of sun and heat and have to be replaced, but this can be minimised by avoiding hot spots. Another option would be to use a grade of plastic that is more resistant to sunlight. The two bottom layers of plastic tend to form tiny tears unless one is very careful in handling them, (that is why there are two layers on the bottom). A tiny hole may let a little water through and dampen the solid insulation, but this is not a big problem.

There are many variations of the solar puddle. We've been able to put the top layer of plastic into a tent-like arrangement that sheds rain. This would be good in a place that gets frequent brief showers. Adding a second insulating layer of air makes the device work even better, though this adds the cost of an extra layer of plastic. As mentioned the device can cover a larger or smaller area if more or less water is desired. One could make a water heater by roughly tripling the amount of water so that the maximum temperature was only 120° F or so, and this water would stay warm well into the evening hours. This water wouldn't be pasteurised though. One could help solve the problem of dirty water vessels by putting drinking cups into the solar puddle and pasteurising them along with the water. The solar puddle could possibly cook foods like rice on an emergency basis, perhaps in a refugee camp.

The “Easy Lid” Solar Cooker.

Designed by Chao Tan and Tom Sponheim

Although designs for cardboard cookers have become more simple, fitting a lid can still be difficult and time consuming. In this version, a lid is formed automatically from the outer box.

Making the Base

Take a large box and cut it in half as shown in Figure 1. Set one half aside to be used for the lid. The other half becomes the base.

Figure 1

Fold an extra cardboard piece so that it forms a liner around the inside of the base (see Figure 2).

Figure 2

Use the lid piece as shown in Figure 3 to mark a line around the liner.

Figure 3

Cut along this line, leaving the four tabs as shown in Figure 4.

Figure 4

Glue aluminium foil to the inside of the liner and to the bottom of the outer box inside.

Set a smaller (inner) box into the opening formed by the liner until the flaps of the smaller box are horizontal and flush with the top of the liner (see Figure 5). Place some wads of newspaper between the two boxes for support.

Figure 5

Mark the underside of the flaps of the smaller box using the liner as a guide.

Fold these flaps down to fit down around the top of the liner and tuck them into the space between the base and the liner (see Figure 6).

Fold the tabs over and tuck them under the flaps of the inner box so that they obstruct the holes in the four corners (see Figure 6).

Figure 6

Now glue these pieces together in their present configuration.

As the glue is drying, line the inside of the inner box with aluminium foil.

Finishing the Lid

Measure the width of the walls of the base and use these measurements to calculate where to make the cuts that form the reflector in Figure 7. Only cut on three sides. The reflector is folded up using the fourth side as a hinge.

Glue plastic or glass in place on the underside of the lid. If you are using glass, sandwich the glass using extra strips of cardboard. Allow to dry.

Figure 7

Bend the ends of the wire as shown in Figure 7 and insert these into the corrugations on the lid and on the reflector to prop open the latter.

Paint the sheet metal (or cardboard) piece black and place it into the inside of the oven.

Improving Efficiency

Glue thin strips of cardboard underneath the sheet metal (or cardboard) piece to elevate it off of the bottom of the oven slightly.

Cut off the reflector and replace it with one that is as large as (or larger than) the entire lid. This reflects light into the oven more reliably.

Turn the oven over and open the bottom flaps. Place one foiled cardboard panel into each airspace to divide each into two spaces. The foiled side should face the centre of the oven.

Drinking Water Collection Systems.

Getting adequate drinking water can often be a problem as there are many places where the local water supply is heavily contaminated with poisons, deadly organisms or both. While it is definitely much better to drink purified water than seriously contaminated water, it should be understood that most of the systems mentioned here, produce either distilled water or something very close to distilled water. Drinking distilled water for more than a few weeks is not ideal as distilled water is able to dissolve almost anything and it can do that perfectly well inside your body, removing essential minerals and other important items. So, if possible, avoid drinking distilled water for lengthy periods of time unless there is no other option other than seriously contaminated water carrying diseases and poisons.

One solution introduced for an area where there is almost never any rainfall is particularly interesting. This region gets fogs in the early morning, so plastic devices were constructed to take advantage of this fact. The devices were like plastic clothes brushes with long, slender vertical projections. The fog encountering these, condenses into freshwater droplets on the surface of these vertical fronds and run down the fronds into a plastic tank which forms the base of the device. No moving parts. No input power needed, but the result is large quantities of drinking water every morning. There is very little evaporation from the tanks, due to the small surface area of the stored water:

This effect is very noticeable on foggy days where trees drip water extensively due the fog depositing moisture on the leaves and branches.

An emergency measure where water is needed, is to fasten a clean plastic bag around a branch of a tree. Trees lift a large amount of water through their root systems and a good deal of that water exist from the leaves of the tree. The plastic bag intercepts that moisture loss and collects it as clean water:

Another emergency measure is to use a clean plastic sheet and a hole dug in the ground. A clean container is placed in the centre of the hole and the plastic sheet used to cover the hold. The sheet is held around the edges of the hole with stones or any other suitable heavy material – bricks, timber, etc. A weight is then placed in the centre of the plastic sheet, pulling it down into a slope in every direction and forming an inverted peak over the container:

The area under the plastic sheet is heated by the greenhouse effect. Moisture also comes from the earth inside the enclosed hole. The moisture in the air in the cavity condenses on the underside of the plastic sheet. But as the plastic sheet is shaped into an inverted pyramid due to the weight just above the container, the water runs down and drips into the container. Again, no input power required and no moving parts.

While these methods produce good quality water which is effectively distilled water, it should not be considered to be sterile and immediately ready for human consumption, even though any risk from drinking it 'as-is' is likely to be very low. There will always be air-borne pathogens, and the 'clean' components used to collect the water in the first place may not be as clean as was thought. The same applies to the excellent quality water produced by dehumidifiers, where the inner working surfaces cannot be considered sterile after the equipment has been used for any length of time. To raise the water quality, boiling briefly, microwaving the water or it to UV radiation should kill any remaining harmful organisms in the water and make it fit for consumption.

Applying these same methods on a more permanent basis, leads to the construction of devices of the following type:

There can be many variations on this shape. These devices are generally built either with glass lids or the whole construction in acrylic sheet. Here, the greenhouse effect heats the inside of the box, causing evaporation of the water inside. This condenses on the walls and lid of the box, where it runs down and into the clean-water section. Please remember that after a long period of use, the device needs to be cleaned very carefully and to deal with air-borne bacteria, the water could be treated briefly with UV light.

This particular design can be further enhanced as shown on the <http://www.permapak.net/solarstill.htm> web site, where the heating inside the box is upgraded by using black high-temperature silicone to coat the inside of the bottom of the case. The black material absorbs sunlight particularly well and so helps to heat the water. Another enhancement is to place a reflector, possibly made from aluminium foil, behind the unit in order to increase the amount of sunlight or UV radiation reaching the water inside the box:

The web site <http://www.gabrielediamanti.com/projects/eliodomestico---how-does-it-work/> shows details of what is considered to be a very effective, low-cost unit aimed at undeveloped countries. Please visit that site where there is a 'Donations' button which allows you to support this excellent work. The designer Gabriele Diamanti says "Eliodomestico is an open project, free to the people who need it. I would really appreciate if you would like to help me in the development of this project!". It works like this:

Eliodomestico is entirely made from poor, widely available materials. The technologies involved in the production are very simple and popular. This also make the maintenance much easier.

- No electricity
- No filters
- Very easy maintenance
- Good impact on the local economy
- No impact on the environment

Eliodomestico is intended to be an open project

attribution - non commercial - share alike

Very simple systems:

It is usually presumed that quite a bit of expenditure and construction is needed to make a solar still which will purify water. That is not necessarily the case. Here is a design which can cost nothing and which can work well in a sunny location:

This arrangement could hardly be more simple than it is. An inner container is used and it is made either from a dark material or is painted black, preferably, matt black as a shiny black reflects more of the light falling on it than a matt black surface does. In the diagram above, the black stops well short of the top of the inner container, but that is only to show the liquid inside the container and in fact, the inner container will be dark from top to bottom. Because of this dark colour, the liquid inside the inner container gets hotter than the air outside it (which is hotter than the air outside the outer container, due to the greenhouse effect). There is considerable evaporation from the inner container, but as it can't escape, it forms droplets on the inside of the outer container and these droplets slide down and collect at the bottom of the container, forming a reservoir of distilled water which is safe to drink. The construction of this still can be from things which are already to hand. For example, the bottom can be cut off a transparent plastic drinks bottle and used to cover a dark glass drinks bottle standing in an ordinary bowl, as shown here:

It is, of course, essential for the outside of the glass bottle and the inside of the plastic bottle to be completely clean so that they do not contaminate the purified water.

Another variation on this is to use a dark glass jar inside a plastic storage jar, again, placed inside an ordinary bowl as shown here:

Alternatively, a plastic jar with a screw lid can be used upside down and the lid used to replace the bowl. The inner container in this case, happens to be plastic. The capacity of the lid limits the amount of clean water which can be produced at any one time, unless the lid is carefully removed and a larger bowl used to catch the clean water (which means that it would have been easier to use the bowl instead of the lid):

On a larger scale: US patents 2,996,897 (1960) from Elmer Grimes:

and Patent 4,418,549 (1982) from Calice Courneya:

show methods of extracting large amounts of drinking water from moisture in the air:

Another system is using a large Fresnel lens to distill water which is not suitable for drinking. This is possible using the most simple equipment of two glass bottles and a piece of copper tubing. If it is still there, the video at <http://www.youtube.com/watch?v=aXjMAItCMl0> shows the method, though I must admit that I would prefer to take the liquid which he drinks and pass it through the system again to improve it's quality further.

Toribio Bellocq's Water Pump.

A serious problem for farmers and individuals is the cost of pumping water up from a borehole or well. While the combined Lever / Pendulum system of Veljko Milkovic described in Chapter 4 can reduce the amount of effort required by a substantial margin, there are other methods which could be useful.

It was originally thought that water could not readily be pumped to a greater height than 32 feet or so unless the pump was located at the bottom of the pipe. Toribio Bellocq demonstrated in 1924 that this is actually not the case and that water can be pumped to any height using a pump mounted at the top of a vertical pipe. He showed a working system to the Patent Office where an 80-foot vertical pipe was used to demonstrate the principle and having proved the point, he was granted US Patents 1,730,336, and 1,730,337, and later, US Patent 1,941,593 in which he describes chamber devices which can enhance the sonic wave operation.

Toribio's system is very straightforward. He places a one-way ball valve at the bottom of the vertical pipe (item **V** in the diagram below). A crank rod is then used to vibrate piston **C** in its pumping cylinder. The pumping cylinder has no valves and the piston stroke is very short. Both the pipe and the pump cylinder are filled with water before the operation is begun.

The rapid movement of the piston creates a pressure wave in the water in the pipe. The pressure wave causes the water pressure inside the pipe to rise and fall rapidly. This altering water pressure at the one-way valve at the bottom of the pipe, causes water to be drawn into the pipe when the pressure is low and the valve prevents the water flowing out again when the pressure rises.

This repeating action causes water to be pumped up the vertical pipe and out through an adjustable valve **R**. When the pumping action is timed correctly, there is an almost continuous flow of water from the pipe.

Toribio quotes an example in his patent, where the vertical pipe has an internal diameter of one inch, placed in a well where the water is twenty metres below the ground level. The valve opening is 30 mm and the sealing ball of the valve has a diameter of about 38 mm and contained in an ordinary cage which allows some 20 mm of vertical movement of the valve.

With this arrangement, the piston at the surface has a diameter of 50 mm and a stroke of 38 mm and is driven by an electric motor at about 360 rpm. The outflow pipe has an internal diameter of half an inch and the valve **R** is used to control the rate of flow out of the system. When the valve is adjusted correctly, a continuous flow is achieved and the flow rate is about 1,000 litres per hour (265 US gallons per hour, or 220

Imperial gallons per hour). It is important that the initial filling of the pipe and fully-open piston avoids getting any air trapped along with the water. The compressor cylinder can be horizontal or vertical. The well can be of any depth and there is no need for the pipe to be straight or vertical. When the system is adjusted correctly, there is little or no wear on the valve at the bottom of the pipe. The liquid pumped does not have to be water.

Richard Dickinson's Water Pump.

US Patent 2,232,678 of 1937, show a very similar system with a piston being driven in a cylinder without valves, creating a pressure wave in the vertical pipe which has a similar one-way valve at the bottom of the pipe. Interestingly, no mention of Bellocq's patent is made. Dickinson's patent drawing of the system outline is shown here:

Arthur Bentley's Water Pump.

The grandson of the car designer, Arthur Bentley has some 34 patents to his name, one of which (US 4,295,799) is very much like Toribio Bellocq's pump system. Richard Bruner writing in the Calgary Herald newspaper in 1989, tells how a prototype of the Bentley design was tested on a Navajo reservation in Arizona. Driven by four solar panels, a flow rate of 120 US gallons per hour was achieved, (about half that of Bellocq's rate at 20 metres depth), though the depth of the Navajo well was not mentioned. The manufacturers claim that the pump can operate at depths of up to 4,000 feet.

Neither this Bentley patent nor his earlier patent 3,804,557 makes any mention of Bellocq which seems somewhat strange, especially with the marked apparent similarity between the designs. Again, we see here, a piston being used to generate an acoustic wave in the vertical pipe and a series of one-way valves at the bottom of the tube being used to trap the rising column of water and prevent it from flowing out of the bottom of the pipe again. A variation in this patent is the addition of a spring loaded bottom section to the pipe which is alternately compressed and expanded by the sound waves as part of the pumping process as shown in the following diagrams:

The Ram Self-Powered Pump.

In hilly areas, it is frequently necessary to pump water up to locations where it is needed. These locations are usually considerably higher than the source of water. There is a simple device called a "Ram Pump" which is powered by water flow alone and needs no other form of power. In a way, it operates very much like the pumps just described, in that water flowing into a pressure chamber causes fluctuating pressure which with just two valves, and no other moving parts, pumps water to a considerable height.

A Ram Pump can be used if there is a fast-flowing stream of clean water, and more than 50% of the water flow into the pump can be lifted to a higher level. The remainder of the water flows back into the stream at a point lower down. These pumps are readily available commercially and interestingly, they have a COP of infinity as the user does not have to supply any input power and yet substantial pumping power is produced for an unlimited period. As this is a standard Engineering technique, nobody gets upset at the thought of 'perpetual motion' or 'free-energy' even though the pump can go on pumping for years with absolutely no fuel being burnt. This is energy being drawn from the environment in the same way as a self-powered compressed air engine draws energy from the environment, and yet, the compressed air engine is considered to be "unbelievable" while the Ram Pump is accepted without question. Could there be a certain degree of bias being seen here? The power operating the pump comes from the water flowing down hill. The water arrives at this height by falling as rain. The rain gets up there by evaporation caused by water being heated by the sun. So, bottom line, the pumping power comes from the sun.

If a fast-flowing stream is not available but the terrain allows it, then a Ram Pump feeding system can be built. Ideally, there should be a drop of at least two metres (six feet) on the inlet pipe. This creates a fast flow into the pump by feeding it through a steeply sloping intake pipe, like this:

Diagram from: www.thefarm.org/charities/i4at/lib2/hydrpump.htm

The performance of a Ram Pump is impressive even though it has only two moving parts. With an input fall of just four metres and a small flow rate of just three litres per minute, a Ram Pump can deliver 69 litres per day to a massive height of 100 metres vertically above the pump. Or, 159 lpd to 60 metres above the pump, or 258 lpd to a height of 40 metres above the pump. This is impressive for such a simple device.

It operates by the water rushing into the air chamber. This raises the pressure until the valve at the base of the chamber slams closed. The increased pressure in the chamber pushes water out of the delivery outlet, lowering the pressure again. While this is happening, the closed valve causes a 'water-hammer' wave of reverse pressure which pushes excess water out of the 'waste' pipe and pushes water back up the intake pipe. When the pressure wave in the intake pipe dissipates, the water rushes back down the pipe, pushing the valve at the base of the air chamber, open again, to repeat the cycle. This oscillating pressure wave causes the pumping action, very much in the same way as the previous pumps which use a mechanical oscillator pump as no free-flowing water is available to create the oscillation.

Commercial ram pumps have an efficiency of about 66%. The calculation of performance is:

$$D = (S \times F \times E) / L$$

Where:

- D** = The quantity of water in litres delivered in 24 hours.
- S** = The quantity of water, in litres per minute, fed to the pump.
- F** = The height in metres of the water source above the pump intake.
- E** = The efficiency of the pump (assume 33% for home built units).
- L** = The height in metres, of the supply outlet above the pump.

Reproduced here by kind permission of US AID 1982 from the web site shown in the diagram above, is a table of values, calculated from the formula above, and assuming the 66% efficiency of a commercial unit. The input flow for these numbers is a tiny 1 litre per minute trickle. This is less than the hydroxy gas rate produced by the Smack's Booster shown in Chapter 10, so in practice, you will be multiplying the numbers in this table by a realistic number of inflow litres per minute.

Litres Delivered over 24 Hours												
Working Fall (m)	Lift - Vertical Height to which Water is Raised Above the Ram (m)

Discouraging Mosquitoes and Small Flies

Maurice Cotterell (whose work is in chapter 11) presents what is a quite remarkable effect. He says:

What it is, is a church door in Ireland, surrounded with a white plastic pipe filled with water. When in Palenque in Mexico Maurice found that the local people discouraged flies, particularly mosquitoes and very

small flies, by hanging polythene bags filled with water, from the lintels of their open doors. They do not know why, but doing that discourages flies from entering the doorway.

Maurice considered the effect and his opinion is that small flies can be injured by raindrops and so they have learned to avoid them. A falling raindrop has an electrogravitic effect due to the hydrogen atoms in the water, and flies which can see in the ultraviolet spectrum, can detect that effect around water and their instinct makes them avoid water – whether falling as droplets or not. Large bluebottle flies do not seem to be affected, but there is a definite effect with smaller flies.

If a doorway is surrounded with a 1-inch (25 mm) diameter plastic pipe filled with water, as seen in the picture above, then Maurice believes that the resulting effect is like this:

Here, gravity waves spread out from the water and create an effective barrier all the way across the doorway, discouraging the smallest flies, including midges. Obviously, any opening can be surrounded with a water-filled pipe, and not just doorways. While this is not a renewable energy device as such, it is a method which could well be useful where serious diseases are carried by mosquitoes.

Wave Power.

Although not generally thought of as an option for personal use, wave power does have a high potential, although, like wind power and unlike tidal power, not always available. We tend to think of wave power systems as being large scale and very expensive, but that is not always the case. At its most basic level, most wave power system uses the varying distance between the surface of an ocean or sea and some fixed point on land or the sea bed.

Ideally, there should be a minimum of moving parts. One neat design uses a simple rectangular concrete housing with an electrical generator mounted above sea level. The generator being above sea level is easy to reach for maintenance or replacement and there are no moving parts underwater. It is a very simple design which can be built quite easily. In its most simple form, it is just a rectangular box with an underwater opening:

Here, a large opening allows the sea to flow into the structure which makes the water level inside the box move up and down with the wave motion outside. As a wave passes by, it compresses the air inside the box and the air is driven out through the generator opening, spinning the generator blades in the same way as a wind-powered generator has it's blades spun by the wind.

Some generators operate well with the air flowing backwards and forwards through the blades, generating electricity no matter which way the blades are spun. With a generator which works better with just one direction of spin, then a large flap valve is installed and it allows air to flow into the structure when the water level is falling but closes immediately the water level starts rising again.

Even though this style of wave power generator is so simple, it works very well in practice, provided that the vertical dimensions are arranged so that the top of the underwater opening is below the lowest neap tide and the bottom of the generator opening is above the highest spring tide. A baffle arrangement can be used to protect the generator from spray and storm debris. There is no need to have the structure full width above the water level:

This has the very considerable advantage that the area of the water surface inside the structure is very much larger than the cross-sectional area of the generator housing column and so the air rushes out through the generator much faster than the wave rises. This amplification factor can be increased by increasing the length of the base of the unit, further enlarging the water surface area inside the structure. If wave action is frequently very strong, then it may be preferred to have the undersea opening facing inshore or sideways in order to reduce the amount of material driven into it by very strong surges.

Another fairly simple wave power generator system design which is based on simple principles, was suggested on Stefan Nystrom's website which has been discontinued. It is called the "WaveReaper" system. It operates using a large number of separate buoys. Plastic barrels are suggested as suitable buoys but almost any non-dangerous containers which will not corrode in the sea and which have a considerable internal volume, can be used in this system.

Each basic unit consists of a float, a pulley, a cable and a ratchet drive connection to the shaft of an electrical generator. The power provided by the movement of the buoy can be very substantial as sea water weighs a considerable amount. The connecting cable is kept taught by a heavy weight, and the cable runs over a pulley which is mounted on a shaft which connects to the shaft of the generator. Bicycle parts are suggested for this section of the drive as they are cheap and readily available in most places and they come with a toothed sprocket wheel which already has a suitable ratchet built into it.

The reason for the shaft is that a whole series of buoys are used. These buoys are positioned progressively further and further from the shore so that an incoming wave raises the buoys one after the other in a regular sequence. This means that while one buoy is letting its cable run back inshore (pulled by its inshore weight), one or more of the other buoys will be rising and applying drive to the shaft linked to the generator. This arrangement allows the generator shaft to receive a continuous drive. Having a heavy flywheel on this shaft is an added advantage as it will smooth out the repeated drive strokes provided by the buoys:

Having a sheaf of moving cables threaded through the sea near the shore is asking for a major tangle with seaweed and all kinds of other drifting material. Very sensibly then, Stefan suggests that the cables be housed in a protecting pipe. Considerable care needs to be taken to make sure that the cables do not rub against anything as the movement is constant and the forces involved are high. Each cable needs to have its own space keeping it clear of all the other cables and having a pulley mounted at any points where there is a change of direction.

To make maintenance easier, it is also suggested that these protecting pipes are not fixed in position but are themselves on a pulley system so that they can be hauled ashore:

The buoys are also linked together loosely on top with a securing cord so that they always stay in a compact group, though there is little chance of any great sideways movement as the tension in the buoy cables is high. Stefan requests that anyone who constructs his design makes a donation via <http://www.o2gruppen.se/> though how that is done is by no means clear to me as there does not appear to be a "Donate" button on that website.

There are many other wave-power devices, some with excellent efficiencies, but most are not generally capable of construction by the average amateur. One example is the "Nodding Duck" design by Stephen Salter of Edinburgh in Scotland, and shown in the US patent 3,928,967 where the wave power is extracted by a raft-like construction with cam-shaped floats. These floats have a rippling movement on the surface of the water and the movement of each section relative to the other sections is used to generate power. This is not exactly a back-yard construction.

Other Systems.

Not included in this eBook, but on the website <http://www.free-energy-info.tuks.nl/> there are articles from the highly recommended Home Power website <http://www.homepower.com/home/> which are on this general topic. There is a system for producing blocks of ice using sun power alone and no other energy input at all:

Above: Steven Vanek with his machine which uses solar thermal energy to make ice.

Also, a two-part article on Solar cooling, which concentrates on heat absorption with different colours, the strategic positioning of buildings and vegetation, practical roof overhangs and the like, to lower the temperature inside buildings in very hot locations.

There are articles is on cooking with hydrogen, heating your house with hydrogen and using hydrogen with a barbecue. On the Home Power site there is information on how to use solar power to heat household water and you may find the Google video on how to make your own hot-water solar panel interesting and useful. It makes sense to reduce your essential costs by doing a few simple things which help.

Cooling Using Heat.

Most of our current refrigerators use electricity to drive a compressor to achieve cooling. Here is a patent from Albert Einstein (whom you may have heard of) and Leo Szilard which uses heat to power refrigeration instead of electricity. It is US Patent 1,781,541 titled "Refrigeration" and dated 11th November 1930.

terminates in a distributor head **31**. Pipe **30** runs inside pipe **5** so that there is a heat exchange between the fluids in those two pipes.

Pipe **32** runs upwards from the lower part of generator **29** to connect with a container **33** which is positioned at a level which is above that of condenser **6**. A source of heat **36**, is applied to pipe **32** at a point above generator **29**. Pipe **37** runs down from container **33**, passing through the heat-exchanger jacket **28** and then on up to the top of condenser **6** where it terminates in a distributor head **35**. Pipe **37** runs inside the cooling water jacket **12** so that the fluid passing through it will be cooled as it flows. A venting pipe **34** connects the upper part of container **33** with the upper part of condenser **6**.

The operation of the apparatus is as follows:

A suitable refrigerant, for example, butane in liquid form, is held inside the evaporator **1**. An inert gas, such as ammonia, is introduced into evaporator **1** through pipe **30** and its distributor head **31**. The refrigerant evaporates in the evaporator in the presence of the inert gas due to the fact that the partial pressure of the refrigerant is reduced thereby and the resulting gaseous mixture passes through pipe **5** and into condenser **6**. Here, the mixture comes into intimate contact with an absorption liquid, for example, water, which is fed into the condenser through pipe **37** and its distributor head **35**. The ammonia gas is very soluble in water but the butane is quite insoluble, so the ammonia is absorbed into the water freeing the butane from the gaseous mixture. Thus, the butane assumes substantially the entire pressure inside the condenser, and that pressure is sufficiently high to cause its liquefaction at the temperature maintained by the cooling water.

The specific gravity of liquid butane is less than that of the solution of ammonia in water and so stratification of the two liquids occurs with the liquid butane floating on top of the ammonia solution **26**. The liquid butane passes from condenser **6**, through pipe **11**, and returns to evaporator **1**, where it is again evaporated and the cycle repeated.

Gravity causes the ammonia solution to flow from condenser **6** through pipe **27** and heat-exchanger jacket **28**, into generator **29**. Here, the application of heat causes the ammonia to be expelled from the solution in the form of a gas, which then passes through pipe **30** and distributor head **31**, into evaporator **1**, where it reduces the partial pressure of the butane, causing it to evaporate as already described.

Water, containing very little ammonia in solution, passes from generator **29** through pipe **32** where it is further heated by the source of heat **36**. This heating causes the formation of vapour in pipe **32** which lifts the liquid through this pipe and into container **33** and on from there under gravity through pipe **37** to condenser **6** and during its flow, this hot, low-concentration liquid is cooled by the heat-exchanger jacket **28**. It is further cooled by the cooling water in jacket **12**, and so reaches a condition where it can rapidly absorb ammonia in the condenser **6**. Vapour entering container **33** through pipe **32**, continues on its journey to the condenser **6** via the venting pipe **34**.

During the operation of this piece of equipment, the pressure existing in the various components is uniform with the exception of slight differences caused by columns of liquid needed to cause the fluids to flow. The pressure existing in generator **29** must be sufficiently greater than the pressure in the upper part of evaporator **1**, in order to make vapour flow through distributor head **31**. In other words, the pressure difference must be sufficient to overcome the liquid head marked h_2 . This excess pressure in the generator is balanced by the pressure created by the column of liquid marked h_1 in the drawing. This means that h_2 must be less than h_1 , otherwise there would be no flow.

This patent of Einstein and Szilard seems to indicate that any source of heat such as a fire or a solar oven, should be able to produce cooling using a device which has no moving parts. It would probably be necessary to provide a trickle of water through the water cooling jacket, but apart from that, it looks like a device which could be used effectively by people who live "off the grid" and have little or no access to electricity. All in all, it is an interesting design.

Solar Panels.

A very well-known method of producing electricity from what appears to be a renewable resource are solar panels. It hardly seems worth mentioning these as sales are so well promoted but it is possible that the problems with them are not understood. This is the most expensive way of producing electricity, and when there is a government scheme to cover one third or one half of the purchase price, it is quite likely that the chosen supplier has prices which are so high that it is cheaper to buy the panels direct from an outlet with competitive pricing rather than paying a much higher price with a subsidy.

What is often not realised is that solar panels have a working life span and will need replacement at some later date. The life is quite good, typically ten to fifteen years, but the price is so high that replacement costs must be allowed for. Solar panels are not the only part of your electrical system which will need replacing. Generally speaking, solar panels are used to charge batteries which then power equipment, usually by using an "inverter" which changes a DC battery voltage to a mains voltage AC supply. The big snag is that the frequently used lead-acid batteries generally have a lifespan of about four years. They are expensive, heavy and as they contain lead, they are not easy to dispose of (legally). This is a major recurring cost and disposal problem.

Another point which may not be realised is that the current which can be drawn from a battery without reducing its working life is very limited. The safe discharge rate is called the "C20" rate which just means that the allowable current is one which discharges the battery in a period of 20 hours. For example, if a new battery is rated as being a 100 Amp-hour ("100 Ahr") battery, then the safe discharge rate is 100 amps divided by 20, which is 5 amps. At twelve volts, a current of five amps is a power output of sixty watts. A washing machine needs about 2,200 watts for at least some of the time, so to power it (and nothing else at the same time) would take 37 of those 100 Ahr batteries. Could you conveniently house 37 large batteries? How much do you think it would cost to replace them every four years?

Another point which is often missed is that batteries are by no means 100% efficient and that means that you have to put more current into them than you can draw out of them afterwards. After some time in use, you may only get between 50% and 80% of the power back from the battery bank.

Please understand that I have nothing against solar panels and actually own three of them myself, but you need to be aware of the practical problems with using them and not imagine that buying them will give you free electricity for ever afterwards.

The next factor to be considered is the fact that the power "rating" of a panel such as "120 watts" is not the amount of power which will be provided by the panel. It will provide that amount of power IF it is positioned exactly square-on to very strong sunlight in a region near the Equator. If the panel is not aimed exactly at the sun, then the panel output will be considerably lower. The sun moves around at a rate of fifteen degrees per hour, so your panel will only be aimed directly at the sun for about four minutes unless you have it mounted on a rotating platform and you push the platform round slowly to face the sun at all times. While that sounds complicated, it is actually not a difficult or expensive thing to arrange although most people don't bother to do that.

Even though most solar panels operate on UV rather than visible light, any minor cloud cover drops the panel output quite noticeably. There is also the little detail that most solar panels only work in sunlight or with reduced output in very bright daylight. This means half the day does not contribute to electrical input and in winter, when the electrical need is greatest, the days are shortest, sunlight scarce and daylight quality very poor unless you live near the equator. The level of sunlight which you will receive drops off steadily the further you get from the equator as the light angle gets lower and lower. This also causes problems in winter with quite low obstacles casting a shadow on the panels and cutting the working time for the panel even further.

The effect of all this is that you will need a far greater claimed panel wattage than your needs seem to require and I would suggest that you probably need between two and three times as many panels as the stated panel wattage would suggest that you need. Considering that chapter 10 shows how to run a generator on water, it would be cheaper to buy and replace a generator on a regular basis than to buy batteries and panels and having to replace them. A generator also runs at night and through the winter.

However, if you are installing solar panels, please be aware that there are considerable differences between panels which have the same apparent rating. A key factor is the voltage produced by the cell under normal working conditions. This makes the difference between a good charging rate under poor conditions and a near-zero charging rate at those times. The good panels have a greater number of cells and the higher voltage produced can make a major difference, so check out the technical specification document on each panel you want to consider and pay attention to the voltage figures and not just the (maximum possible) "wattage" quoted by the manufacturer or sales person. The panels which I picked are made by Kyocera but do your own checking as designs change from year to year. At the present time, solar panels are only about 17% efficient which means that 83% of the power reaching them does not go to make electricity.

Solar panels change size during the day and so need to be mounted in such a way that allows for this expansion and contraction during the day and night. As you don't want to over-charge a battery, it is

generally considered essential to use a control circuit to prevent this happening. In real life, when you use the electricity generated on a daily basis, there is little or no chance of over-charging, but you can decide this for yourself.

One recent development is to use the solar panel(s) to drive a battery-pulsing charging system. This has the major advantage that battery charging does not stop when the light falling on the panel produces a voltage which is too low to charge the battery bank directly. With a pulsing unit, the charging pulse voltage is largely independent of the input voltage and so a good charging rate can be produced in poor lighting conditions, including twilight. This can extend the battery charging period very substantially, especially in winter when there is less light. At this time, one of John Bedini's companies is offering these units for sale.

Assessing solar panels generally from the standpoint of knowing what the snags are, unless you live in a very good location on the planet and have a good deal of spare money to spend, then they are not a great solution, but this is something which you also need to decide for yourself.

However, having said that, a scheme has recently been introduced in the UK and it appears to be a realistic option. Under this scheme, the householder does not buy the solar panels but merely pays to cover the cost of installing them. For example, this house:

has twenty-one panels mounted on the roof and the total cost to the home owner was just £500. The home owner receives a very much reduced electricity cost and expects to recover the installation cost within two years. Even in November at latitude 52 degrees North, these panels are performing well.

Not having to pay for the purchase of the panels themselves makes an enormous difference to the viability of such an installation. I understand that the strategy behind this scheme is to increase the presently tiny percentage of electricity which is produced from renewable sources, by offering people a scheme which actually makes it worthwhile to have an installation.

Chapter 15: You Are Being Deceived

Without your knowledge, you were stolen from your parents at birth and automatically became the judicial property of a commercial company pretending to be your government. What you think of as “your” birth certificate is **proof** of this action. The biggest secret is that your government is a collection of commercial companies whose only real purpose is to take as much money from ordinary people as they can, using unlawful actions. Their sole intention is to keep you poor, in fear and doing whatever they tell you to do.

The Situation in the UK

This is a large subject, so let's take it step by step and start with people who were born in the UK. I will discuss the position of a typical native of what is called “The United Kingdom of Great Britain and Northern Ireland”. The average person living in this area believes that he is a free person living in a democracy which is governed by elected parliamentary representatives of the people, protected by legal statutes introduced by Parliament and enforced by police officers who are there to ensure your protection where physically possible. Those who are better informed, believe that the Magna Carta signed in 1215 affords them substantial rights and freedoms.

None of that is true. Not a single item.

The inhabitants of this region fall into two categories which are “landowners” and “everyone else”. The term “landowner” is, of course, ridiculous. No human can own land. The only way that you can own something is if you create it from materials which you own, if it is given to you as a gift by the rightful owner, or if you buy it from the rightful owner.

If I state “I own the whole of the planet Mars” it does not give me any genuine ownership of the planet. What has happened on planet Earth is that an individual stakes out an area and says “This is my land, I own it, and I will kill anyone who says that I don't”. That can certainly frighten most people away from the area, but it does **not** give the squatter genuine ownership of the land. Consequently, no human owns any land whatsoever, and it is not possible for any land to be bought as there is no previous human owner of the land in question.

Killing a squatter on the land and claiming ownership of that land by right of conquest is farcical. It is true that violent bully-boys take control of areas of land through intimidation and peaceful people dare not oppose them. No human has any more rights than any other human, but violence and the threat of violence have been used to create a notional group of people called “landowners”. Is it right? Is it just? No, of course not, but it is what has happened.

This violent situation resulted in there being two groups of humans in the country. The violent “landowners” called “Knights”, “Lords”, “Barons” or some other irrelevant title, who join together to maintain what they have taken, and then there are the other people who have been intimidated by them, sometimes called “serfs”, whom the landowners feel free to rob on a regular basis through sheer intimidation.

Already, there was a certain degree of deception being practiced by the landowners as they said to the serfs “we will protect you, and in return, you can work for us and pay us to protect you. This, of course, was a complete con, because if it wasn't for the landowners, there would be no need at all for “protection” from other landowners. And, oh yes, the protection required the serfs to put their lives on the line as part of the “protection” racket.

There was one group of landowners who operated more by trickery than by sheer force of arms. Going under the general title of the “Church” their influence came from telling people that when they die that they would not go to “heaven” if they were not servants of the Church. That technique worked very well and even influenced the head honcho of the landowners - the Monarch who was the ultimate “landowner”. Don't get me wrong. I'm not saying that it is wrong to worship God, follow a moral code, live an upright and blameless life, **but**, doing that has nothing whatsoever to do with being subject to any human or human organisation.

A point which you have probably missed is that the ‘landowners’ considered the serfs to be sub-human “things” and not people at all. Unfit to, and incapable of, owning land under any circumstances. Considered to be ‘goods and chattels’ owned by the landowners. At that time, “serf” was an alternative word for “slave”.

It is not possible for one human to genuinely “own” another human. Parents do not own the children born to them. They have a duty and a responsibility to nurture them and care for them and ideally, love them, but they do not

own them. The weird notion which landowners have that they “own” humans is as false as anything can get. Slavery is another act of violence. Only a very ill-informed person believes that slavery has been ‘abolished’ as it is more widespread today than at any other time in all of recorded history, and it has nothing whatsoever to do with skin colour.

In the well-known year of 1066, another violent ‘landowner’ arrived in England and by force of arms, imposed Roman law on all of England. You will recall that Rome was very heavily into slaves and the slaves had no rights or privileges, no possessions and no protection, in spite of the fact that in reality, every one of them actually had equal entitlement to the rights claimed by their so-called “owners”, both slaves and masters being human beings. So, please understand clearly, that Roman law encompassed the notion of people being called slaves, and owned as “things”.

In 1213, King John was excommunicated and that frightened him so much that he signed a contract with the Pope. The contract is known as the “Treaty of Verona” and it undertook to introduce Rome’s canon law to England, which made Archbishop Stephan Langton, the effective ruler of all of the country. The contract was supposed to give the Pope ownership of all of the lands, people, animals, etc. of all of King John’s kingdom. According to this contract, the Vatican owns all of England and all of the British Commonwealth countries.

This is, of course, a rubbish document. Firstly, King John did not genuinely own any land of any description and never could have. Secondly, King John did not and never could have owned any of the people living on that land. Thirdly, a contract cannot be signed on behalf of a third party, so his signature could never, ever have any genuine effect on the people of the land. If that were not the case, then I could sign a contract on your behalf, guaranteeing that you would pay me a million pounds. It couldn’t happen and if it did, it would be meaningless. The Treaty of Verona contract only applies to the signing parties, to have any effect on the people of the land would require them to be fully informed of the consequences and give their consent to the contract, and that never happened.

In an attempt to be cunning, the treaty was worded so as to make it appear to apply to the direct descendants of both the English monarch and the direct descendents of the Pope, namely, his successors. Personally, that seems highly doubtful to me as that would make it, in effect, a contract between people who have not agreed to it or signed it, and it is by no means obvious how a contract could be binding on people who are not party to it and who have not signed it.

However, just two years later in 1215 the landowners forced King John to sign a contract called the “Magna Carta”. It is highly doubtful that a contract where one of the parties is intimidated into signing, has any actual validity, but that aside, the contract was made under the conditions prevailing at that time. The landowners, called “Barons” or “Free men” in the document, were insisting on a continuing agreement between them and the monarch. The contract has nothing to do with the serfs who were considered “things” with no rights at all. Today, members of the general public, who are actually the descendants of those serfs, read the Magna Carta and not understanding the situation when it was written, mistakenly think that it speaks of them. It doesn’t. The objective was actually an attempt to strengthen the Treaty of Verona.

This power-play continued in 1600 when a private company was set up. It is still in place today and it is called “The Ministry of Justice” D-U-N-S Number 22-549-8526, Directors: Lord Falconer of Thoroton. Today, all Magistrate Courts are private for-profit companies subsidiaries of this main commercial company and not, as most believe, part of the government of the UK.

The next step came in 1689 with the “Bill of Rights” whose purpose was to make the monarch subject to Parliament. Again, this was introduced with the intention of ensuring that no monarch could set aside the Treaty of Verona and deny the Pope (supposed) ownership of the British empire and all the people in it. The Bill of Rights settled the succession of the crown, creating a Dynasty which has been maintained right up to now. The only powers of a Constitutional Sovereign created by this “Bill of Rights” is to warn, to guide and to be informed, just that and nothing else. In 1701 there was the Act of Settlement to confirm the line of royal succession.

In 1694 a privately owned company called “**The Bank of England**” was formed. The name gives the impression that it is a government organisation, but that is not the case. Actually, the UK has no government but instead there is a set of interlocking, privately owned, for-profit commercial companies designed to give the false impression of a government. For example, **the House of Commons** is a commercial for-profit company (number UC2279443). **The Labour Party** is a commercial company which trades under the name of “Allister Darling MP”. **The House of Lords** which is the highest court in the land is a private company.

Then there is the **United Kingdom Corporation Ltd.**, formerly known as the “United Kingdom plc”. In passing, anyone who has a National Insurance Number, is automatically deemed to be an employee of the United Kingdom Corporation Ltd. The Company policy of that corporation requires each employee, to pay tax and follow all the

legislative rules (“statutes”) of that corporation. Anyone who breaks the rules of the corporation will be disciplined under the legislation of that corporation.

The police forces of the United Kingdom Corporation are all companies which can be seen from their company registrations, and their job is to enforce the rules of the Corporation. **Every court** in the land is a company. There is a commercial company called the “**Secretary of State for Trade and Industry**”, which ceased trading on 4th November 2002 and yet it still operates TV licensing, taking £3 billion per year through it’s subsidiary commercial private limited company called “Consignia (Customer Management) Ltd.”, which is part of it’s group of 35 subsidiary companies.

This continues to a ridiculous level where the company called “**The Devon and Cornwall Police**” has been taken over by a company called SouthWestOne which is one of a group of companies whose Ultimate Parent Company is IBM, but this Police Constabulary is a public service paid for by the taxpayer and given an annual budget of £256,800,000 taken from members of the public. Isn’t IBM a lucky company to be given £256,800,000 per year to help it run it’s business at a profit !

Equally ridiculous is the **Lancashire County Council** which was incorporated as a company (IP00666C) in 2002. It’s registered office was 3rd Floor, Christ Church Precinct, County Hall, Preston. It was completely dissolved on 25th January 2008 and all of it’s Assets and Liabilities were transferred on 12th November 2007 to another company - “The Blues and Twos Credit Union Ltd.” whose registered address is Lancashire Police Headquarters, PO Box 77, Hutton, Preston.

The screenshot shows the Companies House search results page. At the top, there's a navigation bar with links like 'Home', 'Bookmark site', 'Links', 'About us', 'Forms', 'Press Desk', 'Careers', and 'Contact us'. Below this is a search bar with the text 'Select Search Results on "LANCASHIRE COUNTY COUNCIL"'. A message says 'To obtain further details, click on the appropriate company number below.' Below this is a search form with fields for 'Company Name' and 'Company Number' (which has 'IP00666C' entered). There are checkboxes for 'Alpha Index' and 'Enhanced Index', and a section for 'Choose only one for Alpha Index Enquiries' with checkboxes for 'Current / recently dissolved names', 'Dissolved names', 'Previous names', and 'Proposed names'. Below the search form is a table with columns 'Number', 'Status', 'Name', and 'Action/Event : Date'. The table shows two entries for 'LANCASHIRE COUNTY COUNCIL' with status 'C' and 'D'. The 'D' entry has an action of 'Company Removed' on '25/01/2008'. Below the table is another search form identical to the one above. At the bottom, there's a footer with contact information: 'Contact Centre +44 (0)303 1234 500 available 08:30 to 18:00 (UK time)' and an email address.

Number	Status	Name	Action/Event : Date
IP00666C	C	LANCASHIRE COUNTY COUNCIL	
IP00666C	D	LANCASHIRE COUNTY COUNCIL	Company Removed Dissolved 25/01/2008

If you feel that these things are all straightforward and aboveboard, then I would like you to change a bundle of £3 notes for me, and as well, perhaps you would be interested in buying the Eiffel Tower.

The ordinary people resident in the UK are descended from the slaves called “serfs” and the only protection which they have is the “Common Law”, upheld by a policeman or a policewoman, each of whom receive authority through, and only through, their personal oath of allegiance to the monarch and the monarch’s oath to uphold Common Law. The Police Authority for whom the policeman or policewoman work, actually has no authority itself as, being a company, it cannot swear an oath. Policemen and policewomen have a duty to uphold Common Law and to protect and serve members of the public.

UK Common Law deals with a human causing death or injury to another human, damage to property or acting fraudulently in dealings with others. It is based mainly on the earlier findings of courts and is modified from time to time if it is found to be unjust. Surprisingly, the main corrections are supposed to come, not from judges, but from juries. A jury is the most powerful element in any court of law for they have the power to dismiss a case and even to go against the law. A jury has “discretion” and they can order the judge to find against the law if they believe that in the particular case which they are trying, the law would be unfair, so they adjudicate on both the individual case **and** on the underlying law. Judges do not always bring this to the attention of jurors.

A system has been set up by the Law Society with the express intention of enslaving members of the general public. They have taken words from the English language and redefined them to create another language called "Legalese".

The translation for this language back into English is given in the publication "Black's Law Dictionary". The average member of the UK public is generally unaware that Legalese is being spoken and that what sounds like a simple, innocuous question in English, is actually a highly-loaded and underhand attempt to cause him both distress and unwarranted financial loss.

The objective of a lawyer is to make money for his commercial company and particularly for himself. To help them, lawyers have set up a system of "statutes" which are supposed to have the force of law, but which, being crafted by their sister parliamentary commercial companies, are **not** the law. These things are "statutes" and they don't actually apply to humans. Being wholly invented "legal" devices, they only apply to other "legal" things, which are essentially, just pieces of paper. Since a piece of paper does not own any money or goods, to get any real financial gain from their actions, they need to trick a human into taking on responsibility for a piece of paper. If they succeed in this, then they can demand money from that piece of paper and get the unfortunate human to actually provide the money even though the fictitious legal charges do not apply to that human.

Meet Your Strawman

In order to do this, they have to persuade the human to enter into a contract with them, agreeing to pay them money, essentially, for nothing in return. Their main trick is creating a fictitious legal identity using the name of the human. This is done by creating a "Birth Certificate" in the same name. Most parents mistakenly believe that they **have** to register the birth of their child, which is actually **not** a requirement under the law (which **does** apply to humans, as opposed to "statutes" which don't apply to humans).

In spite of their mistake, the fictitious legal "person" produced by creating the Birth Certificate document, the human who has the same first and last names as those recorded on the birth certificate, has no actual link to that document unless he can be tricked into agreeing to be linked to it.

All of the company statutes such as Income tax, Council tax, television licence, parking tickets, and the like are not being charged against a human but instead are being charged against the legal fiction with nearly the same name, sometimes called a "strawman". If the human refuses to agree that there is a link, then the invented charges collapse and the human is left alone until the next attempt to fool him. At this time there is a very nicely produced video <http://www.youtube.com/watch?v=ME7K6P7hlko> which explains the fiction of the strawman legal document.

The people who work for one of the commercial companies called Police Forces have two entirely different roles. As a policeman or policewoman they have a duty under common law to protect members of the public, and serve them by upholding common law. They have an entirely different role as a police **officer** dedicated to making money for their employer by imposing all kinds of fines, charges and penalties under a series of statutes invented by their sister companies. These financial penalties do not actually apply to humans, and so trickery must be employed in order to con the human into undertaking to pay when there is no requirement for the human to do so.

A Police **Officer** is a corporate employee who acts as a Revenue Collector for the Corporation and enforces Acts of Parliament.

A Police **Community Support Officer** is a Corporate employee who has no powers whatsoever, and holds no Oath of Office. They are given a Warrant Card and told to keep it because while they don't need it now, they will need it at some point in the future. Without an oath to the monarch, they have no authority at all.

The British people live in a "common law jurisdiction". This means that no Civil Law Statute applies to them at any point **unless the individual consents to it**. If asked to give your name, do not do so as that is a trick which places you into the realm of civil law which does not apply to you at all unless you consent to be placed under it. You are not obliged under common law to answer the question which asks your name and/or address. The police officer will be following training and may well not be aware that trickery is involved, never having been trained in common law and their duties under it, to each member of the public.

The Comments of John Harris

John Harris of the <http://www.tpuc.org/> web site makes the following points:

The deception of “Joinder” or more aptly named “pretensive joinder”: The human is asked for his full name, address and date of birth in order to establish the LEGAL PERSONALITY, the address of the LEGAL PERSONALITY and the date on which the LEGAL PERSONALITY was created. Once Joinder has been established, they can then offer that LEGAL PERSONALITY a contract. But, they need the consent of the human to act on behalf of the fictitious LEGAL PERSONALITY and so the human is asked “do you UNDERSTAND?” The human is then required to sign at least one piece of paper saying that he is the LEGAL PERSONALITY and that as the LEGAL PERSONALITY, he UNDERSTANDS.

This is deception as “UNDERSTAND” is taken to mean “STAND UNDER” and has nothing to do with the human comprehending anything. During any process where a human has any dealing with Corporation Officers, he is asked “do you understand?” and that is simply about **consent**. He is being asked to represent the LEGAL PERSONALITY and give the Corporate Officer authority over him.

The deception of “Notice”: In Legalese, a “notice” is not a bill or a demand, instead, it is an offer of contract. When the offer has been made, the LEGAL PERSONALITY must be established through Joinder because the LEGAL PERSONALITY is only a piece of paper. Consequently, the human has to agree to represent that piece of paper by saying “I understand”. Fixed penalty notices are the same as all, and any, statements made: they are simply, self-perpetuating Contracts. Making a statement to police is exactly the same - a self-perpetuating contract.

The deception of “Includes”: The Inclusion of one is the Exclusion of another – this is a maxim (an established, unchallengeable fact). A summons (invitation) for watching TV without a licence has “We will present any evidence found of your watching TV without a licence, which may include a statement taken under caution by one of our Enforcement Officers”. But the legalese “may” translates into “must”, but if you make a statement with your name, address and confirmation of watching TV, then the court issues summary judgement as you have already incriminated yourself and the court has nothing to decide.

The deception of “Summons”: Summons is synonymous with “invitation” which is a choice. They are inviting a LEGAL PERSONALITY to a Corporate place of business. The LEGAL PERSONALITY is just a piece of paper, a BIRTH CERTIFICATE created by the United Kingdom Corporation and it is **not** the human. You can’t be forced into a contract, so they have to deceive you into entering into one without realising what you are doing. They are using deception as every Magistrates Court is a trading name of the commercial company called “The Ministry of Justice” D-U-N-S Number 22-549-8526 which does not have a Parent Company listed meaning that it is a Parent Company. Directors: Lord Falconer of Thoroton, date of incorporation 1600. Legal people on being shown this registration, responded by saying that if this information is genuine (which it is), then the UK has been lawless for more than 400 years because the whole Justice System is being dealt with by a company.

Deception of the Name: If you go to a Court (which is a Corporate place of Business) as the Accused, you will be asked to confirm your Name, quoting the full name shown on your birth certificate, which is the LEGAL PERSONALITY. Titles such as Mr, Dr, Lord, PC, QC, or whatever are not asked for as they are not required. The “Accused” is actually the LEGAL PERSONALITY which is the name on the birth certificate, so when they ask for the person’s NAME, they are talking to the LEGAL PERSONALITY and **not** the human. This is because a human **cannot** exist in the legal world - only pieces of paper can, and that is something which they are very careful not to tell you.

This is a really key issue. Natural Law and Common Law are the only laws which apply to humans and they deal only with harming other people or causing them loss, and outside of those restrictions, a human has free and unlimited entitlement to do anything he chooses which complies with these principles. As opposed to this, Acts of Parliament, “Statutes” and Statutory Instruments “Contracts” do not apply to the human but only to the piece of paper which is the LEGAL PERSONALITY and which has no reality. As the legal fiction of the LEGAL PERSONALITY was created by the company called “the United Kingdom Corporation”, it is that company which gets to say what the rights and duties are for that piece of paper.

The deception of the Birth Certificate: When a person is born in Britain, the mother and father submit a Birth Certificate Registration Form, which is a piece of paper. There is no requirement under common law to do this. When any limited company or corporation is set up, there is always a Certificate of Registration in order to create it’s LEGAL PERSONALITY and that is a piece of paper. Please note that a British Birth Certificate states quite clearly that it is **not** evidence of identity, that is, it has nothing to do with a human. Marked on it is “Crown Copyright” showing clearly that it does not belong to an individual and was created by “the crown” which is not the monarch but is the independent ‘City of London’ represented by the Law Society and acting on behalf of the private owners. This act of Registering a child, makes that child a “ward of the court” which means that the child can be taken away from the parents at any time.

The deception of Registration: If I lawfully own a vehicle, then it cannot be taken away from me and crushed as that would constitute a criminal act and considered theft, no matter who takes it. However, if I Register my vehicle, then, without realising it, I hand ownership of the vehicle over to the registering company as a free gift. They acknowledge the gift by issuing me with a piece of paper stating that I am "the Registered Keeper" of their vehicle, to which they assign a number in their registration records of the vehicles which they own (although they will not pay for the upkeep of their vehicles).

John also asks:

Do you believe Parliament is elected to Represent the people and their wishes? It isn't, they are Directors of a commercial 'for-profit' corporation and so, nothing will ever change.

Do you believe in Politics? There is no such thing.

Do you believe that the only way to sort the UK out is to elect a different Political Party? It makes no difference as all you are doing is choosing employees of a commercial company, and the owners dictate what the company does, no matter who the corporate serving officers may be.

Do you believe that Acts of Parliament ("Statutes") are Law? They aren't.

Do you believe that Statutory Instruments are Law? They aren't.

What The UK Police Can, and Can't Do

Posted September 26th, 2008 by Guy_Euden

Do you feel intimidated when pulled over? Do you feel intimidated when stopped in the street? Do you feel that you are obliged to give them information or answer their questions? If your answer is "yes" to any of these questions, then you **don't** know your rights. A police officer is not what he was many moons ago. In bygone days they cared for their employers (yes you), they actually wanted to help you, they wanted to solve crimes, they had compassion, a sense of fair play and in response to this they earned our respect and admiration.

ALL of that has changed! Police officers are now Revenue Agents plain and simple and if any police officer is silly enough to think that's not true, or just wish to profess it isn't, then let him try not giving out fixed penalties for a month and see if a talking to is not the result! The truth is that they are now your adversary and that is not meant in a violent way, more like a game of who can get who to do as they're told, and they are trained to get from you what they need in order to actually fine or arrest you by actually getting you to consent to it. Let's quickly look at all laws that don't include Death or Injury to others, Damage to another's property or using fraud in your contracts.

OK, these three very heavy crimes are all you can truly be guilty of - YES it's all you can truly be guilty of!!! Anything else is just STATUTE LAW and the simple to remember definition of this law is "laws that only apply if you consent to them"!! Here, look at the definition of a Statute: "Legislative rule of society given the force of law **by the consent of the governed**". Yes look at the last four words, "CONSENT OF THE GOVERNED" that is you!! So, if you don't consent, then they can't do anything. Yes, I know what you're thinking, but it really **is** that simple. Ok, an officer walks up to you and says "can I ask you some questions?" Don't consent. Ask him "what is the nature of the intended detention?". Record the conversation and let him see that you are doing this. Use your mobile, as 99% of mobile phones available today have recorders so go for it! If he says that you cannot record this conversation, then what he is in fact saying is, "yep you guessed it - I don't consent to be recorded!!". So, you simply say "Ok, am I free to go?"

The simple fact is that they **need** your consent, and they have some very cool tools to use to get it, one is intimidation, and another is acting. They act like they are your friend. They act like they care. They just ACT! This is to put you off guard and most people sing like canaries!! Their other weapon of choice is Inconvenience. You don't have time to waste playing their game, so you talk in order to get away quicker, and wham! - they have their result! If you are pulled over for an offence under an act, for example, speeding, seatbelt or some other infraction, it is all part of the "Road Traffic Act of 1988 keyword is "ACT" and believe you me what a merry old act it is, it is pure stage play.

When issuing a ticket they **need** your name so SHUT UP! Don't argue with them as that is "adversarial" so just SHUT UP! They need your name and date of birth to confirm which corporation they are going to give the bill of exchange to (bills of exchange defences are simple but we are not doing those right now). So don't provide a name, or date of birth, or address. Don't give them anything to work with, don't say a single word no matter what coercion they try, hell they might even go for some "good cop bad cop" stuff this is great to watch when you are

fully aware of their lack of power, it's like watching "EastEnders". If they read you your rights you have to say that you understand in order for handcuffs to be put on you. **Again, your consent is necessary** (get it?) don't say a word!!

Now these Officers of Revenue don't like the grim realisation that they have no power. You could get arrested, yes I am afraid that they can still arrest you, but the worst that they can do is keep you for a few hours, so get some sleep, oh and if you have a "notarised claim of right, with a schedule of charges for arrest and detention", then sleep even sweeter because these fools are paying you to learn that they have no power! I know that getting arrested isn't nice, they know this, that's why it's one of their tools to get you **to consent to their unnecessary and unlawful penalties**.

But if you don't stay quiet, then they will always have power over you. Now if they are going to arrest you, one nice way of them playing into your hands is if you say these few words: "Officer, I am a peaceful man, there will be no violence, but you are obliged to note that if you are going to arrest me it will be under protest and duress at all times and I reserve all of my rights at all times, and I waive none of those rights at any time for any cause or reason". If they take you to the station remember **DON'T SAY A SINGLE WORD**. Hell you might get a new name! "JOHN DOE". If they try to fingerprint you, tell them that you do **not** consent to this. If they try to get your DNA then tell them that you do **not** consent to this. If they touch you, tell them, "Officer I do not consent to be touched at all".

If you make it known that you know your rights then they will leave you alone. Trust me, they will only act illegally if you continue to let them do so. Remember that any "legal" acts that they choose to quote are powerless, a clawless, toothless tiger.... they have no power if you don't consent.

Summary:

The present UK (and world) situation is designed to confuse you. The UK is a "Common Law jurisdiction" which has had a spurious and fake "legal" system added on to it in order to rob you blind. The average inhabitant of the UK is bound to keep the common law or suffer the consequences. The common law requires a human not to kill or injure another human, not to damage or steal his property and not to swindle him.

The spurious "legal" system introduced by the Law Society (who consider all other humans as inferiors), is designed to steal from those humans by deception and fraud. It operates by tricking humans into inadvertently and unknowingly entering into a contract to pay money to someone who will not provide anything of worth in exchange.

This is done by using the legalese language which has taken words from the English language and changed their meanings without making the changes of meaning made clear to the public. This covert and surreptitious method is used to get a human to represent a legal fiction which is a piece of paper and undertake to pay invented debts attached to that piece of paper.

The average UK resident believes that there is a UK government, when in fact, there is no actual government, just a commercial company pretending to be a government, namely, the company called "The United Kingdom Corporation Limited". People are fooled into "voting" for the election of corporate officers in this company in order to make them believe that there actually is a government where no government exists.

This hateful "legal" system is there solely to enslave and rob ordinary people living in the UK and there appears to be no way to circumvent it. I have seen a calculation which estimates that on average, ordinary people in the UK have 80% of their income taken from them in taxes. So, for every £100 they earn, they only receive £20.

A self-employed person may be able to avoid paying Income Tax, Council Tax, TV licence and some other minor taxes. An employed person is tied to a "legal entity" employer which cannot escape the legal snare and so is forced to take Income Tax, National Insurance and Child Support amounts off a person's earned payment before the remainder is given to the employee.

Unfortunately, even self-employed people can't escape the thieves because they add their massive charge on to essential items which are not sold to people by name. For example, I have been told that 85% of the cost of a gallon of fuel for a vehicle is tax. That means that if I buy £100 of fuel, it really should have only cost me £15 as that is the cost of finding it, extracting it, refining it, transporting it and making a profit on selling it. My £85 has been taken against my will, by people who are not entitled to it.

If I buy almost anything in a shop, then 17.5% of the selling price is taken from me and given to someone who doesn't deserve it. In reality, it is much more than that because the item purchased was transported to the shop using fuel which was heavily taxed, and I have to pay that tax indirectly in the raised cost of the item. Also, the

shop has to have heating and lighting, both of which are powered by heavily taxed fuel, which raises the price which I have to pay on the item. Then, there is the tax on the company and the tax on the company for having employees, both of which have to be covered in the price which I am charged. You can see why the person who costed out how much is really paid in tax, came up with an overall figure of 80% of a person's earned income. Even a self-employed person can't escape paying a major amount of indirect tax. The often-quoted phrase "we live in a free country" does not seem to have any basis in fact. So, how about "the land of the brave and the land of the free" across the Atlantic ocean, do they fare any better?

The Situation in America

In 1606, King James I the King of England set up a commercial enterprise called "The Virginia Company" with himself as the main stockholder. The Virginia Company was formed in anticipation of the imminent influx of white Europeans, mostly British at first, into the North American continent. The Virginia Company of London (also called the "London Company") was chartered by King James with the object of colonising the eastern coast of North America between latitudes 34°N and 41°N. Its shareholders were Londoners. The Virginia Company claimed ownership of most of the land that we now call America. The Virginia Company (the British Crown and the bloodline families) claimed rights to 50% of all gold and silver mined, plus percentages of other minerals and raw materials, and 5% of all profits from other ventures.

As has been already remarked, no human can own land as there is no way that genuine title to the land can be bestowed on any human, short of God giving him a written deed of ownership as a gift. No human can buy land from another human or organisation as they didn't genuinely own the land in the first place. King James was essentially, no different from any other man and he had no justification for blithely claiming ownership of another country. Even being the first squatter on the land (which he wasn't) does not give any man ownership of that land. Consequently, his was, and is, a spurious claim with no basis in fact or any form of justification.

At this time, America does not have a government because "The UNITED STATES" is a commercial company. The term "United States" means a Federal corporation. The US President is the President of a commercial corporation and American citizens are, in effect, the employees of that Corporation. This present situation was sneaked in by the covert actions of the Americans who organised and ran the civil war with the intention of taking lands and assets from people who lived in the South. Most people imagine that, say, Virginia, is a part of the American nation under the American government. However, this is not true as every one of the "States" is actually set up as a commercial, for-profit, company, under the parent company "The United States of America". So the reality is that instead of being a State of the Nation, the "State of Virginia" is the name of a commercial for-profit company.

The Vatican claims that it owns Britain and all of the commonwealth countries. Britain claims that it owns America as a British colony. The King of England provided financial backing to both sides of the Revolutionary war and believed that the lands of the Virginia Company were granted (on lease) to the colonies under a Deed of Trust and therefore they could not claim ownership of the land. They could pass on the perpetual use of the land to their heirs or sell the perpetual use, but they could never own the land itself as ownership was supposedly retained by the British Crown.

You may be interested to know that the Vatican's system of law is based on the ancient Roman system and in Rome, the seat of power for Caesar was called "Capitol Hill" where Caesar would meet with 'the Senate'. The Pope believes that he can abolish any law in the United States (Elements of Ecclesiastical Law Vol. 1, 53-54). The Pope's laws are supposed to be obligatory on everyone.

The conglomeration of privately owned commercial corporations know as "the United Sates of America" go along with the same old ridiculous scam of considering American human beings to be "slaves" under Roman law. Consequently, no American can own property because slaves can't own property. If an American reads the Deed to a property which he thinks that he owns, he will discover that he is listed as a "Tenant" (Senate Document 43, 73rd Congress, 1st Session).

After the first 21 years from the formation of the Virginia Company, all 'duties, imposts and excises' paid on trading activities in the colonies were paid directly to the British Crown through the Crown treasurer. Queen Elizabeth II of Britain, controls and has amended U.S. Social Security: Statutory Instrument 1997 No. 1778 The Social Security (United States of America) Order 1997.

The American Inland Revenue Service Publication 6209 is form 1040 which is to be used for tribute paid to Britain. Americans are considered to be slaves to the Queen and own absolutely nothing (Senate Document 43). America's Social Security is not insurance or a contract, nor is there a Trust Fund. The criminal courts on the lands of the Virginia Company were to be operated under Admiralty Law, the law of the sea, and the civil courts under common law, the law of the land. This is a crucial point. The United States of America is not a country, it is

a corporation owned by the same Brotherhood bloodlines who owned the Virginia Company, because the USA is considered to be the property of the Virginia Company.

There is a "USA" which is the 68 square miles of land west of the Potomac River on which is built the federal capital, Washington DC and the District of Columbia, also the US protectorates of Guam and Puerto Rico. And then there is a "usA" the "united states of America" which are the lands of the various states. These lands are still supposedly owned by the British Crown as the head of the Virginia Company.

The Act of 1871 created a new, altered Constitution. The title was changed to capital letters and the word "for" was changed to the word "of". That is, "The Constitution for the united states of America" was altered to "THE CONSTITUTION OF THE UNITED STATES OF AMERICA".

An American cannot use the Constitution to defend himself because he is not a party to it. "The People" does not include ordinary U.S. Citizens. The Act of 1871 also created a separate form of government for the District of Columbia, which is a ten mile square parcel of land which is governed with British Admiralty law, U.C.C. (Acts of the Forty-First Congress, Section 34, Session III, chapters 61 and 62).

When Americans agree to have a Social Security Number, they surrender their sovereignty and agree to become franchisees of the United States (which is supposedly the Virginia Company of the British Crown). Americans are led to believe that there is only one United States and that the Federal government is the rightful government. The use of lower/upper-case characters is making a legal statement. If you are American, then you should notice that when you receive any correspondence relating to government, law or anything to do with finance or taxation that your name is always spelt entirely in block capitals.

Your name in block capitals is not you. It is a corporation set up by the 'government' Corporation through the treasury department at the time of your birth. Any time that a child is born, a corporation/trust is created using his or her name in block capitals. One definition of "a human being" is "a corporation treated as having the rights and obligations of a person" while the definition of a "natural person" is 'a real human being', as distinguished from a corporation, which is often treated at law as being a fictitious person.

Everything in the "United States" is "For Sale": roads, bridges, schools, hospitals, water, prisons, airports, etc. (Executive Order 12803). Americans are Human capital (Executive Order 13037).

The Emergency Banking Relief Act of 9th March 1933, defined the American people as legally, the **enemy** of the United States Government and the private, international Federal Reserve System became the Government of the United States.

The national flag of the United States always has a gold fringe when displayed in court or federal buildings, federally-funded schools and the uniforms of US troops. Under the International Law of the Flags, a gold fringe indicates the jurisdiction of commercial law, also known as British Maritime Law, and in the US as the uniform Commercial Code or "UCC".

George Bush launched a 'war on terrorism' on behalf of a private Corporation, to further the goals of that Corporation. It had nothing to do with 'America' or 'Americans', because those are very different legal entities. The United States Corporation owns the United States military and everything else that comes under the term 'federal'. It is not the duty of the US police to protect Americans. Their job is to protect the Corporation and arrest code breakers (Sapp v. Tallahassee, 348 So. 2nd. 363, etc.). There are no Judicial courts in America and there have not been since 1789. Judges do not enforce Statutes and Codes but instead, Executive Administrators enforce Statutes and Codes. The most powerful court in America is not the United States Supreme Court but instead, it is the Supreme Court of Pennsylvania (42 Pa.C.S.A. 502). Pennsylvania is the keystone state.

The FCC, CIA, FBI, NASA and all similar organisations were never part of the United States government, even though the "US Government" held shares of stock in the various Agencies. (U.S. v Strang, 254 US 451, Lewis v US, 680 F.2d, 1239).

Americans may think that their government and legal system is pegged in some way to the Constitution, but it is not. The United States, like Britain and elsewhere, is ruled by commercial law to overcome the checks and balances of common law. It is a monumental fraud.

The web site http://www.youtube.com/watch?v=klwWcp9eiPw&feature=player_embedded lists what it considers to be a series of little-known facts about America. It says:

"The IRS is not a U.S. government agency. It is an agency of the IMF which in turn is an agency of the United Nations. The United States has **not** had a Treasury since 1921 as the U.S. Treasury is now the IMF. The United States does not have any employees because there no longer is a United States. The FCC, CIA, FBI, NASA, etc.

were never part of the U.S. government but are privately owned companies. US Social Security numbers are issued by the UN through the IMF, (the SS5 form does not state who issues it). There have been no Judicial Courts in America since 1789. There have been no Judges in America since 1789. According to GATT, Americans must have a Social Security Number. New York City is defined in the Federal regulations as the United Nations. Social Security is not insurance or a contract and Social Security cheques come directly from the IMF which is an agency of the UN.

All Americans are slaves and so can own absolutely nothing, not even what they think of as being their own children. The most powerful court in America is the Supreme Court of Pennsylvania. The King of England financially backed both sides of the Revolutionary War. Americans can't use the US Constitution to defend themselves because they are not a party to it. Britain is owned by the Vatican and the Pope claims to own the entire planet through the laws of conquest and discovery (Papal Bulls of 1495 and 1493). The Pope has ordered the genocide and enslavement of millions of people (Papal Bulls of 1455 and 1493). The Pope's laws are obligatory on all Americans. "The People" does not include ordinary Americans. (Barron v City Council of Baltimore 32 US 243)".

When you become aware of these things, it becomes easier to understand why voting in a Presidential election can never make any difference - after all, he is only the President of a commercial company whose corporate policy is set by the owners of the company and not by the President. It also explains what these commercial companies have done and are still doing through their agencies such as the CIA.

The fractional reserve policy perpetrated by the Federal Reserve, which has spread in practice to the great majority of banks in the world, is, in fact, a system of modern slavery. Think about it: money is created out of debt. What do people do when they earn debt? They submit to employment to pay it off. But if money can only be created out of loans, how can society ever be debt-free? It can't, and that's the point. And it is the fear of losing assets coupled with the struggle to keep up with the perpetual debt and inflation in the system, compounded by the inescapable scarcity in the money supply itself, created by the interest which can never be repaid, that keeps the wage-slave in line, powering the pyramid which benefits only the elite at the top of the pyramid. At the end of the day, for whom are you really working? The banks. Money is created in a bank and inevitably ends up in a bank. They are the true masters along with the corporations and governments which they support. Physical slavery requires people to be housed and fed, economic slavery requires people to house and feed themselves.

Michael Rivero has put together a concise statement on the situation in America, and his statement is at <http://whatreallyhappened.com/WRHARTICLES/allwarsarebankerwars.php> where he says:

I know that many people have a great deal of difficulty with understanding just how many wars are started for no other purpose than to force private central banks on to nations, so let me share a few examples, in order that that you can understand why the US Government is engaged in so many wars against so many foreign nations. There is ample precedent for this.

The United States fought the war of the American Revolution primarily over King George III's Currency Act, which forced the colonists to conduct their business only using printed bank notes borrowed from the Bank of England at interest. After the revolution, the new United States adopted a radically different economic system in which the government issued its own value-based money, so that private banks like the Bank of England were not siphoning off the wealth of the people through interest-bearing bank notes.

"The refusal of King George 3rd to allow the colonies to operate an honest money system, which freed the ordinary man from the clutches of the money manipulators, was probably the prime cause of the revolution". -- Benjamin Franklin, Founding Father

But bankers are nothing if not dedicated to their schemes to acquire your wealth, and they know how easy it is to corrupt the leaders of a nation. Just one year after Mayer Amschel Rothschild had uttered his infamous statement: *"Let me issue and control a nation's money and I care not who makes the laws"*, the bankers succeeded in setting up a new Private Central Bank called the First Bank of the United States, largely through the efforts of the Rothschild's chief US supporter, Alexander Hamilton.

Founded in 1791, by the end of its twenty year charter the First Bank of the United States had almost ruined the nation's economy, while enriching the bankers. Congress refused to renew the charter and signalled their intention to go back to a state-issued value-based currency on which the people paid no interest at all to any banker. This resulted in a threat from Nathan Mayer Rothschild against the US Government: "Either the application for renewal of the charter is granted, or the United States will find itself involved in a most disastrous war". Congress still refused to renew the charter for the First Bank of the United States, whereupon Nathan Mayer Rothschild railed, "Teach those impudent Americans a lesson! Bring them back to colonial status!"

Financed by the Rothschild-controlled Bank of England, Britain then launched the war of 1812 to re-colonise the United States and force them back into the slavery of the Bank of England, or to plunge the United States into so much debt they would be forced to accept a new private central bank. The plan worked. Even though the War of 1812 was won by the United States, Congress was forced to grant a new charter for yet another private bank issuing the public currency as loans at interest, and that was the Second Bank of the United States. Once again, private bankers were in control of the nation's money supply and cared not who made the laws or how many British and American soldiers had to die for it.

Once again the nation was plunged into debt, unemployment, and poverty through the plundering of the private central bank, and in 1832 Andrew Jackson successfully campaigned for his second term as President under the slogan, "Jackson And No Bank!" True to his word, Jackson succeeds in blocking the renewal of the charter for the Second Bank of the United States.

"Gentlemen! I too have been a close observer of the doings of the Bank of the United States. I have had men watching you for a long time, and am convinced that you have used the funds of the bank to speculate in the breadstuffs of the country. When you won, you divided the profits amongst you, and when you lost, you charged it to the bank. You tell me that if I take the deposits from the bank and annul its charter I shall ruin ten thousand families. That may be true, gentlemen, but that is your sin! If I let you go on, you will ruin fifty thousand families, and that would be my sin! You are a den of vipers and thieves. I have determined to rout you out, and by the Eternal, (bringing his fist down on the table) I will rout you out!" -- Andrew Jackson, shortly before ending the charter of the Second Bank of the United States. From the original minutes of the Philadelphia committee of citizens sent to meet with President Jackson (February 1834), according to Andrew Jackson and the Bank of the United States (1928) by Stan V. Henkels

Shortly after President Jackson (the only American President to actually pay off the National Debt) ended the Second Bank of the United States, there was an attempted assassination which failed when both pistols used by the assassin, Richard Lawrence, failed to fire. Lawrence later said that with Jackson dead, "Money would be more plenty".

Of course, the present day American public school system is as subservient to the bankers' wishes to keep certain items of history from you, just as the corporate media is subservient to Monsanto's wishes to keep the dangers of Genetically Modified foodstuffs from you, and the Global Warming cult's wishes to conceal from you the fact that the Earth has actually been cooling for the last 16 years. Thus it should come as little surprise, that much of the real reasons for the events of the Civil War are not well known to the average American.

When the Confederacy seceded from the United States, the bankers once again saw the opportunity for a rich harvest of debt, and offered to fund Lincoln's efforts to bring the south back into the union, but at 30% interest. Lincoln remarked that he would not free the black man by enslaving the white man to the bankers and using his authority as President, he issued a new government currency, the "greenback". This was a direct threat to the wealth and power of the central bankers, who responded quickly.

"If this mischievous financial policy, which has its origin in North America, becomes entrenched, then that Government will issue it's own money without cost. It will pay off debts and be without debt. It will have all the money necessary to carry on it's commerce. It will become prosperous to a degree which is without precedent in the history of the world. The brains, and wealth of all countries will migrate to North America. That country must be destroyed or it will destroy every monarchy on the globe". -- The London Times responding to Lincoln's decision to issue government Greenbacks to finance the Civil War, rather than agree to private banker's loans at 30% interest.

In 1872 New York bankers sent a letter to every bank in the United States, urging them to fund any newspapers which opposed government-issued money (Lincoln's greenbacks): *"Dear Sir: It is advisable to do all in your power to sustain such prominent daily and weekly newspapers... as will oppose the issuing of greenback paper money, and that you also withhold patronage or favours from all applicants who are not willing to oppose the Government issue of money. Let the Government issue the coin and the banks issue the paper money of the country...To restore to circulation the Government issue of money, will be to provide the people with money, and will therefore seriously affect your individual profit as bankers and lenders".* -- Triumphant plutocracy; the story of American public life from 1870 to 1920, by Lynn Wheeler

"It will not do to allow the greenback, as it is called, to circulate as money any length of time, as we cannot control that". -- Triumphant plutocracy; the story of American public life from 1870 to 1920, by Lynn Wheeler

"Slavery is likely to be abolished by the war, power, and chattel slavery destroyed. This, I and my European friends are in favour of, for slavery is but the owning of labour and carries with it the care for the labourer, while the European plan, led on by England, is for capital to control labour by controlling the wages. THIS CAN BE

DONE BY CONTROLLING THE MONEY". -- Triumphant plutocracy; the story of American public life from 1870 to 1920, by Lynn Wheeler

Goaded by the private bankers, much of Europe supported the Confederacy against the Union, with the expectation that victory over Lincoln would mean the end of the Greenback. France and Britain considered an outright attack on the United States to aid the confederacy, but were held at bay by Russia, which had just ended the serfdom system and had a state central bank similar to the system the United States had been founded on. Left free of European intervention, the Union won the war, and Lincoln announced his intention to go on issuing greenbacks. Following Lincoln's assassination, the Greenbacks were pulled from circulation and the American people forced to go back to an economy based on bank notes borrowed at interest from the private bankers.

Finally, in 1913, the Private Central Bankers of Europe, in particular the Rothschilds of Great Britain and the Warburgs of Germany, met with their American financial collaborators on Jekyll Island, Georgia to form a new banking cartel with the express purpose of forming the Third Bank of the United States, with the aim of placing complete control of the United States money supply once again under the control of private bankers. Owing to hostility over the previous banks, the name was changed to "The Federal Reserve" system in order to grant the new bank a quasi-governmental image, but in fact it is a privately owned bank, no more "Federal" than Federal Express. Indeed, in 2012, the Federal Reserve successfully rebuffed a Freedom of Information Lawsuit by Bloomberg News on the grounds that as **a private banking corporation** and not actually a part of the government, the Freedom of Information Act did not apply to the operations of the Federal Reserve. The year 1913 proved to be a transformative year for the nation's economy, first with the passage of the 16th "income tax" Amendment and the false claim that it had been ratified.

"I think that if you were to go back and try to find and review the ratification of the 16th Amendment, which was the internal revenue, the income tax, I think that if you went back and examined that carefully, you would find that a sufficient number of States never ratified that Amendment". – U.S. District Court Judge James C. Fox (Sullivan vs United States, 2003).

Later in 1913, apparently unwilling to risk another questionable amendment, Congress passed the Federal Reserve Act over the Christmas holiday, while members of Congress who were opposed to the measure were at home. This was a very underhanded deal, as the Constitution which explicitly grants Congress the authority to issue the public currency, does not authorise it to delegate that authority, and so it should have required a new Amendment to allow Congress to transfer that authority to a private bank. But Congress did pass it, and President Woodrow Wilson signed it (as he had promised the bankers that he would, in exchange for generous campaign contributions). Wilson later regretted that decision, stating: *"I am a most unhappy man. I have unwittingly ruined my country. A great industrial nation is now controlled by its system of credit. We are no longer a government by free opinion, no longer a government by conviction and vote of the majority, but a government by the opinion and duress of a small group of dominant men". – Woodrow Wilson 1919.*

The next year, World War One started, and it is important to remember that prior to the creation of the Federal Reserve, there was no such thing as a world war.

The First World War started between Austria-Hungary and Serbia, but quickly shifted to focus to Germany, whose industrial capacity was seen as an economic threat to Great Britain, who saw the decline of the British Pound as a result of too much emphasis on financial activity to the neglect of agriculture, industrial development, and infrastructure (not unlike the present day United States).

Although pre-war Germany had a private central bank, that bank was heavily restricted, and inflation kept to reasonable levels. Under government control, investment was guaranteed to internal economic development, and Germany was seen as a major power. So, in the media of the day, Germany was portrayed as the prime instigator of World War One, and subsequently, not just defeated, but had its industrial base flattened.

Following the Treaty of Versailles, Germany was ordered to pay the war costs of all of the participating nations, even though Germany had not actually started the war. This amounted to three times the value of all of Germany itself. Germany's private central bank, to whom Germany had gone deeply into debt to pay the costs of the war, broke free of government control, and massive inflation followed (mostly triggered by currency speculators), permanently trapping the German people in endless debt.

When the Weimar Republic collapsed economically, it opened the door for the National Socialists to take power. Their first financial move was to issue their own state currency which was not borrowed from private central bankers. Freed from having to pay interest on the money in circulation, Germany blossomed and quickly began to rebuild its industry. The media called it "The German Miracle". TIME magazine lionized Hitler for the amazing improvement in life for the German people and the explosion of German industry, and even named him TIME Magazine's "Man Of The Year" in 1938.

Once again, Germany's industrial output became a threat to Great Britain, resulting in these comments:

"Should Germany merchandise (do business) again in the next 50 years, we have led this war (WW1) in vain". - Winston Churchill in The Times (1919)

"We will force this war upon Hitler, if he wants it or not". - Winston Churchill (1936 broadcast)

"Germany becomes too powerful. We have to crush it". - Winston Churchill (November 1936 speaking to US - General Robert E. Wood).

"This war is an English war and its goal is the destruction of Germany". - Winston Churchill (- Autumn 1939 broadcast) .

Germany's state-issued value-based currency was also a direct threat to the wealth and power of the private central banks, and as early as 1933 they started to organise a global boycott against Germany to strangle this upstart ruler who thought he could break free of private central bankers!

period I spent more of my time being a high-class muscle man for Big Business, for Wall Street and for the bankers. In short, I was a racketeer, a gangster for capitalism. I suspected that I was just a part of a racket at the time. Now I am sure of it. Like all members of the military profession I never had an original thought until I left the service. My mental faculties remained in suspended animation while I obeyed the orders of the higher-ups. This is typical with everyone in the military service. Thus I helped make Mexico and especially Tampico safe for American oil interests in 1914. I helped make Haiti and Cuba a decent place for the National City Bank boys to collect revenues in. I helped in the raping of half a dozen Central American republics for the benefit of Wall Street. The record of racketeering is long. I helped purify Nicaragua for the international banking house of Brown Brothers in 1909-12. I brought light to the Dominican Republic for American sugar interests in 1916. In China in 1927 I helped see to it that Standard Oil went on its way unmolested. During those years, I had, as the boys in the back room would say, a swell racket. I was rewarded with honours, medals and promotion. Looking back on it, I feel I might have given Al Capone a few hints. The best he could do was to operate his racket in three city districts. I operated on three continents". -- General Smedley Butler, former US Marine Corps Commandant, 1935

As President, John F. Kennedy understood the predatory nature of private central banking, he understood why Andrew Jackson fought so hard to end the Second Bank of the United States. So Kennedy wrote and signed Executive Order 11110 which ordered the US Treasury to issue a new public currency, the United States Note.

Kennedy's United States Notes were not borrowed from the Federal Reserve but created by the US Government and backed by the silver stockpiles held by the US Government. It represented a return to the system of economics on which the United States had been founded, and this was perfectly legal for Kennedy to do. All told, some four and a half billion dollars went into public circulation, eroding interest payments to the Federal Reserve and loosening their control over the nation. Five months later John F. Kennedy was assassinated in Dallas Texas, and the United States Notes pulled from circulation and destroyed (except for samples held by collectors). John J. McCloy, President of the Chase Manhattan Bank, and President of the World Bank, was named as part of the Warren Commission, presumably to make certain that the banking dimensions behind the assassination were concealed from the public.

As we enter the eleventh year of what future history will most certainly describe as World War Three, we need to examine the financial dimensions behind the wars.

Towards the end of World War Two, when it became obvious that the allies were going to win and dictate the post war environment, the major world economic powers met at Bretton Woods, a luxury resort in New Hampshire in July 1944, and hammered out the Bretton Woods agreement for international finance. The British Pound lost its position as the global trade and reserve currency and its place was taken by the US dollar (part of the price demanded by Roosevelt in exchange for the US entry into the war). Without the economic advantages of being the world's central currency, Britain was forced to nationalise the Bank of England in 1946. The Bretton Woods agreement, was ratified in 1945, and in addition to making the US dollar the global reserve and trade currency, obliged the signatory nations to tie their currencies to the dollar. The nations which ratified Bretton Woods did so on two conditions. The first was that the Federal Reserve would refrain from over-printing the dollar as a means to loot real products and produce from other nations in exchange for ink and paper; basically an imperial tax. That assurance was backed up by the second requirement, which was that the US dollar would always be convertible to gold at \$35 per ounce.

Of course, the Federal Reserve, being a private bank and not answerable to the US Government, did start overprinting paper dollars, and much of the perceived prosperity of the 1950s and 1960s was the result of foreign nations' obligations to accept the paper notes as being worth gold at the rate of \$35 an ounce. Then in 1970, France looked at the huge pile of paper notes sitting in their vaults, for which real French products like wine and cheese had been traded, and notified the United States government that they would exercise their option under Bretton Woods to return the paper notes for gold at the \$35 per ounce exchange rate. Of course, the United

States had nowhere near the gold to redeem the paper notes, so on August 15th, 1971, Richard Nixon "temporarily" suspended the gold convertibility of the US Federal Reserve Notes.

This "Nixon shock" effectively ended Bretton Woods and many global currencies started to disengage from the US dollar. Worse still, since the United States had collateralised their loans with the nation's gold reserves, it quickly became apparent that the US Government did not in fact have enough gold to cover the outstanding debts. Foreign nations began to get very nervous about their loans to the US and understandably were reluctant to lend any additional money to the United States without some form of collateral. So Richard Nixon started the environmental movement, with the EPA and its various programs such as "wilderness zones", "Road-less areas", "Heritage rivers", "Wetlands", all of which took vast areas of public lands and made them off limits to the American people who were technically the owners of those lands. But Nixon had little concern for the environment and the real purpose of this land grab under the guise of the environment was to pledge those pristine lands and their vast mineral resources as collateral on the national debt. The plethora of different programs was simply to conceal the true scale of how much American land was being pledged to foreign lenders as collateral on the government's debts; eventually almost 25% of the nation itself.

With open lands for collateral already in short supply, the US Government embarked on a new program to shore up sagging international demand for the dollar. The United States approached the world's oil producing nations, mostly in the Middle East, and offered them a deal. In exchange for only selling their oil for dollars, the United States would guarantee the military safety of those oil-rich nations. The oil rich nations would agree to spend and invest their US paper dollars inside the United States, in particular in US Treasury Bonds, redeemable through future generations of US taxpayers. The concept was labelled the "petrodollar". In effect, the US, no longer able to back the dollar with gold, was now backing it with oil. Other peoples' oil, and the necessity to keep control over those oil nations in order to prop up the dollar has shaped America's foreign policy in the region ever since.

But as America's manufacturing and agriculture has declined, the oil producing nations faced a dilemma. Those piles of US Federal Reserve notes were not able to purchase much from the United States because the United States had little (other than real estate) which anyone wanted to buy. Europe's cars and aircraft were superior and less costly, while experiments with GMO food crops led to nations refusing to buy US food exports. Israel's constant belligerence against its neighbours caused them to wonder if the US could actually keep their end of the petrodollar arrangement. Oil-producing nations started to talk of selling their oil for whatever currency the purchasers chose to use. Iraq, already hostile to the United States following Desert Storm, demanded the right to sell their oil for Euros in 2000 and in 2002, the United Nations agreed to allow it under the "Oil for food" program instituted following Desert Storm. One year later the United States re-invaded Iraq, lynched Saddam Hussein, and placed Iraq's oil back on the world market only for US dollars.

Following 9-11, the clear US policy shift away from being an impartial broker of peace in the Middle East to one of unquestioned support for Israel's aggressions, only further eroded confidence in the Petrodollar deal and even more oil-producing nations started openly talking of oil trade for other global currencies.

Over in Libya, Muammar Gaddafi had instituted a state-owned central bank and a value-based trade currency, the Gold Dinar. Gaddafi announced that Libya's oil was for sale, but only for the Gold Dinar. Other African nations, seeing the rise of the Gold Dinar and the Euro, even as the US dollar continued its inflation-driven decline, flocked to the new Libyan currency for trade. This move had the potential to seriously undermine the global hegemony of the dollar. French President Nicolas Sarkozy reportedly went so far as to call Libya a "threat" to the financial security of the world.

So, the United States invaded Libya, brutally murdered Gaddafi (the object lesson of Saddam's lynching not being enough of a message, apparently), imposed a private central bank, and returned Libya's oil output to dollars only. The gold that was to have been made into the Gold Dinars is, as of last report, unaccounted for.

According to General Wesley Clark, the master plan for the "dollarification" of the world's oil nations included seven targets, Iraq, Syria, Lebanon, Libya, Somalia, Sudan, and Iran (Venezuela, which dared to sell their oil to China for the Yuan, is a late addition). What is notable about the original seven nations originally targeted by the US is that none of them are members of the Bank for International Settlements, the private central bankers private

central bank, located in Switzerland. This meant that these nations were deciding for themselves how to run their nations' economies, rather than submit to the international private banks.

Now the gun sights of the bankers are on Iran, which dares to have a government central bank and sell their oil for whatever currency they choose. The war agenda is, as always, to force Iran's oil to be sold only for dollars and to force them to accept a privately owned central bank.

The German government recently asked for the return of some of their gold bullion from the Bank of France and the New York Federal Reserve. France has said it will take 5 years to return Germany's gold. The United States has said they will need 8 years to return Germany's gold. This suggests strongly that the Bank of France and the NY Federal Reserve have used the deposited gold for other purposes, and they are scrambling to find new gold to cover the shortfall and prevent a gold run. So it is inevitable that suddenly France invades Mali, ostensibly to combat Al Qaeda, with the US joining in. Mali just happens to be one of the world's largest gold producers with gold accounting for 80% of Mali exports. War for the bankers does not get more obvious than that!

Americans have been raised by a public school system and media that constantly assures them that the reasons for all these wars and assassinations are many and varied. The US claims to bring democracy to the conquered lands (they haven't; the usual result of a US overthrow is the imposition of a dictatorship, such as the 1953 CIA overthrow of Iran's democratically elected government of Mohammad Mosaddegh and the imposition of the Shah, or the 1973 CIA overthrow of Chile's democratically elected government of President Salvador Allende, and the imposition of Augusto Pinochet), or to save a people from a cruel oppressor, revenge for 9-11, or that tired worn-out catch all excuse for invasion: "weapons of mass destruction". Assassinations are always passed off as "crazed lone nuts" to obscure the real agenda.

The real agenda is simple. It is enslavement of the people by the creation of a false sense of obligation. That obligation is false because the Private Central Banking system, by design, always creates more debt than money with which to pay that debt. Private Central Banking is not science, it is a religion; a set of arbitrary rules created to benefit the priesthood, meaning the owners of the Private Central Bank. The fraud persists, with often lethal results, because the people are tricked into believing that this is the way life is supposed to be and no alternative exists or should be dreamt of. The same was true of two earlier systems of enslavement, 'Rule by Divine Right' and 'Slavery', both of which are systems designed to trick people into obedience, and both of which are now recognised by modern civilization as illegitimate. Now we are entering a time in human history where we will recognise that 'rule by debt', or rule by Private Central Bankers issuing the public currency as a loan at interest, is equally illegitimate. It only works as long as people allow themselves to believe that this is the way life is supposed to be.

But understand this above all else, Private Central Banks do not exist to serve the people, the community, or the nation. Private Central Banks exist to serve their owners, to make them rich beyond the dreams of Midas and all for the cost of ink, paper, and the right bribe to the right official.

Behind all these wars, all these assassinations, the hundred million horrible deaths from all the wars lies a single policy of dictatorship. The private central bankers allow rulers to rule only on the condition that the people of a nation remain enslaved to the private central banks. Failing that, any ruler will be killed, and their nation invaded by those other nations which are already enslaved to private central banks.

The so-called "clash of civilizations" we read about on the corporate media is really a war between banking systems, with the private central bankers forcing themselves on to the rest of the world, no matter how many millions must die for it. Indeed the constant hatemongering against Muslims lies in a simple fact. Like the ancient Christians (prior to the Knights Templar's private banking system), Muslims forbid usury (the lending of money at interest), and that is the reason why the American government and media insist that Muslims must be killed or converted. They refuse to submit to currencies issued at interest. They refuse to be debt slaves. So off to war American children must go, to spill their blood for the gold of the money-junkies. We barely survived the last two world wars. In the nuclear/bio weapon age, are the private central bankers willing to risk incinerating the whole planet just to feed their greed? Apparently so.

Flag waving and propaganda aside, all modern wars are wars by and for the private bankers, fought and bled for by third parties unaware of the true reason why they are expected to be killed and crippled. The process is quite simple. As soon as the Private Central Bank issues its currency as a loan at interest, the public is forced deeper and deeper into debt. When the people are reluctant to borrow any more, that is when the Keynesian economists demand the government borrow more to keep the pyramid scheme working. When both the people and government refuse to borrow any more, that is when wars are started, to plunge everyone even deeper into debt to pay for the war, then after the war to borrow more to rebuild. When the war is over, the people have about the same as they did before the war, except the graveyards are far larger and everyone is in debt to the private bankers for the next century. This is why Brown Brothers Harriman in New York was funding the rise of Adolf Hitler.

As long as Private Central Banks are allowed to exist, inevitably, as night follows day, there will be poverty, hopelessness, and millions of deaths in endless World Wars, until the Earth itself is sacrificed in flames to Mammon. The path to true peace on Earth lies in the abolishment of all private central banking everywhere, and a return to the state-issued value-based currencies that allow nations and people to become prosperous.

Michael Rivero

The Economic Hit-Men

It is one of the most ingenious scams for social manipulation ever invented, and at its core, it is an invisible war waged against the population, and you will remember that the Emergency Banking Relief Act of 9th March 1933, **defined** the American people as “the **enemy**” of the United States Government. Debt is the weapon used to conquer and enslave societies and interest is its prime ammunition. While the majority of people are not aware of this reality, banks in collusion with governments and corporations continue to expand and perfect their tactics of economic warfare, spawning new bases such as the World Bank and the International Monetary Fund and introducing a new kind of soldier - the economic hit-man.

Here is the testimony of one of those American economic hit-men, John Perkins:

We, the economic hit men, are the ones really responsible for creating the first really global empire, and we work many different ways. Perhaps the most common is that we will identify a country which has resources which our corporations covet, such as oil, and then arrange a huge loan to that country from the World Bank or one of its sister organisations. But the money never actually goes to the country, instead, it goes to our big construction corporations to build infrastructure projects in that country, like industrial power plants, things which benefit a few rich people in that country (in addition to our corporations), but really don't help the people involved, however those people and the whole country are left holding a huge debt so big that they can't repay it, which is the whole plan - that they can't repay it. So we economic hit men go back to them and say “listen, you owe us a lot of money, you can't repay it, so sell your oil real cheap to our oil companies, allow us to build a military base in your country or send troops to some place in the world to support our troops in somewhere like Iraq, or vote with us in the UN to have their electric utility company privatised, or their sewage system privatised and sold to US corporations or other multinational corporations, so there is a whole mushrooming thing and it's the way that the World Bank and the International Monetary Fund operate to put a whole country in debt with such a big debt that it can't pay it, so you then offer to refinance that debt and get them to pay even more interest and you demand this

'quid pro quo' or 'conditionality' or 'good governance' which means basically that they have to sell off their resources, including their social services and utility companies, their school systems sometimes, their penal systems, their insurance systems to foreign corporations. So, it's a double, triple, quadruple whammy.

Examples:

Iran 1953: The precedent for economic hit men began back in the early 1950s when the democratically elected Prime Minister of Iran, Dr Mohammed Mossadegh, was considered to be a hope for democracy - Time Magazine's Man of the Year. One of the policies which he ran on was the idea that the oil companies needed to pay the Iranian people a lot more for the oil which they were taking out of Iran. We didn't like that, of course, but we were afraid to do what we would normally do, which is to send in the military. Instead, we sent in one CIA agent, a relative of President Roosevelt. He went in with a few million dollars and was very efficient and effective and in a short amount of time he managed to get Mossadegh overthrown and brought in the Shah of Iran to replace him. It was extremely effective. So back here in the United States, people in Washington looked around and said "wow - that was easy and cheap !" So this established the whole new way of manipulating countries and creating empire. The only problem with Roosevelt was that he was a card-carrying CIA agent and if he had been caught, the ramifications would have been pretty serious. So, very quickly at that point a decision was made to use private 'consultants', to channel the money through the World Bank, the IMF or one of the other such agencies, bring in people like me who worked for private companies, so that if we got caught, there would be no government ramifications.

Guatemala 1954: When Arbenz (Jacobo Arbenz Guzman) became President of Guatemala, the country was very much under the thumb of the United Fruit Company, the big international corporation and Guzman ran under the strategy of giving the land back to the people. When he was elected he started implementing those policies of giving the land back to the people. United Fruit didn't like that so much, so they hired a Public Relations company in the United States mounted a huge campaign to convince the people of the US, the press of the US and the Congress of the US that Arbenz was a Soviet puppet and if we allowed him to stay in power the Soviets would have a foothold in this hemisphere, which, at that time, was a huge fear on everybody's minds, so to make a long story short, out of this public relations campaign came a commitment on the part of the CIA and the military to take this man out, and in fact, we did. We sent in planes, we sent in soldiers, we sent in jackals, we sent in everything

to take him out, and we did take him out. And as soon as he was removed, his successor reinstated the links to the big corporations including United Fruit.

Ecuador 1981: Ecuador for many, many years was ruled by pro-US dictators, often relatively brutal. Then it was decided that they were going to have a truly democratic election Jaime Roldos (Aguilera) ran for office and his main goal, he said, as President was to make sure that Ecuador's resources were used to help the people. And he won, overwhelmingly, by more votes than anyone has ever won anything in Ecuador and he began to implement these policies to make sure that the profits from oil went to help the people. Well, we didn't like that in the United States. I was sent down as one of several economic hit men to change Roldos, to corrupt him, to bring him around, to let him know "you know, you and your family can get very rich if you play our game but if you but if you continue to try and keep these policies you promised, then you are going to go". He wouldn't listen. He was assassinated "Ecuadorian Leader Dies in Plane Crash". As soon as the plane crashed, the whole area was cordoned off. The only people allowed in were the US military from a nearby base and some of the Ecuadorian military. When an investigation was launched, two of the key witnesses died in car accidents before they had a chance to testify. A lot of very, very strange things went on around the assassination of Roldos. I, like most of the people who really looked at this case had absolutely no doubt that it was an assassination and of course, in my position of an economic hit man, I was expecting something to happen to Jaime, whether a coup or an assassination I was sure that he would be taken down as he was not being corrupted, he would not allow himself to be corrupted the way we wanted to corrupt him.

Panama 1981: Omar Torrijas President of Panama was one of my favourite people. I really, really liked him, he was very charismatic and he really wanted to help his country. When I tried to bribe him, to corrupt him, he said "look, John, he called me Juanita, look Juanita, you know, I don't need the money, what I really need is for my country to be treated fairly. I need the United States to repay the debts which you owe my people for all the

destruction you have done here. I need to be in a position to help other Latin American countries with their independence and be free of this terrible presence from the North. You people are exploiting us so badly. I need to have the Panama Canal back in the hands of the Panamanian people. That's what I want. So leave me alone, don't try to bribe me". It was in 1981 and in May Jaime Roldos was assassinated and Omar was very aware of this. He got his family together and said "I'm probably next, but it is ok because I've done what I came here to do, I've renegotiated the Canal, the Canal will now be in our hands". He had been renegotiating the treaty with Jimmy Carter:

In June of that same year, just a couple of months later, he also went down in an aeroplane crash which there is no question was executed by CIA jackals. There is a tremendous amount of evidence, one of Tarrijas' security guards handed him, at the last moment as he was getting on the plane, a small tape recorder which contained a bomb.

Venezuela 2002: It is interesting to me how this system has continued pretty much the same way for years and years and years except the economic hit men get better and better and better. Then we come up with, very recently, what happened in Venezuela in 1998 when (Hugo Rafael) Chavez gets elected, following a long line of Presidents who were very corrupt and who basically destroyed the economy of the country, and Chavez was elected following all of that. Chavez stood up to the United States demanding that Venezuela oil be used to help the Venezuelan people. Well we didn't like that in the United States, so in 2002, a coup was staged, and there is no question in my mind or in most other people's minds, that the CIA was behind that coup. The way that coup was fermented was very effective, like Colonel Roosevelt had done in Iran - paying people to go out into the streets to riot, to protest and say that Chavez is very unpopular. You know, if you can get a few thousand people to do that, television can make it look like the whole country and things start to mushroom, except in the case of Chavez, he was smart enough and the people were so strongly behind him that they overcame it, which was a phenomenal moment in the life of Latin America.

Iraq 2003: Iraq, actually, is a perfect example of the way the whole system works. We economic hit men are the first line of defence. We go in and try to corrupt governments and get them to accept these huge loans which we then use as leverage to basically own them. If we fail, as I failed in Panama with Omar Torrijas, and in Ecuador with Jaime Roldos, men who refused to be corrupted, then the second line of defence is we send in the jackals and the jackals either overthrow governments or they assassinate and when that happens and a new government comes in, boy, it's going to toe the line as the new President knows what will happen if he doesn't. And in the case of Iraq, both of those things failed and the economic hit men were not able to get through to Saddam Hussein although they tried very hard. We tried very hard to get him to accept a deal but he wouldn't accept it and so the jackals went in to take him out but they couldn't do it as his security was very good. After all, he had at one time worked for the CIA and been hired to assassinate a former President of Iraq and failed, but he knew the system. So, in 1991 we send in the troops and we take out the Iraqi military, assuming that at that point that Saddam is going to come around. We could, of course, have taken him out at that time, but we didn't want to as he is the kind of strong man that we like, able to control his people and keep pumping oil for us. But when we took out his military he didn't come around so the economic hit men go back in the 90s without success. If they had had success, he'd still be running the country - we'd be selling him all the fighter jets he'd want, but they didn't have success. The jackals couldn't take him out again, so we sent the military in once again and took him out, and created for ourselves very lucrative reconstruction deals to rebuild a country which we had essentially destroyed - which is a very good deal if you own a construction company - a really big one. So, Iraq shows the three stages: the economic hit men - failed there, the jackals failed there, so as the final measure, the military goes in.

And in that way, we have really created an empire, but we have done it very, very subtly, it's clandestine. All the empires in the past were built by the military and everybody knew they were building them. The British knew they were building it, the French, the Germans, the Romans, the Greeks - they were all proud of it and they always had some excuse like "spreading civilisation", or spreading some religion, something like that, but they knew they were doing it. We don't. The majority of the people in the United States have no idea that we are living off the benefits of a clandestine empire, that today there is more slavery in the world than ever before.

You may have to ask yourself if it's an empire, then who's the Emperor? Obviously, our Presidents in the United States are not Emperors. An Emperor is someone who is not elected, does not serve a limited term, and who doesn't report to anyone. So you can't classify Presidents that way. But we do have what I consider to be the equivalent of the Emperor in what I call the "Corporatocracy". The Corporatocracy is this group of individuals who run our biggest corporations and they really act as the Emperor of this empire. They control our media (either by direct ownership or by advertising), they control most of our politicians because they finance their campaigns, either through corporations or through personal donations. They are not elected, they don't serve a limited term, they don't report to anybody, and at the very top of the Corporatocracy, we can't tell if the person is working for a corporation or for the government as they are always moving back and forth, so you get a guy who is one moment the president of a big company like Halliburton and the next moment he's the Vice President of the United States, or the President who is in the oil business and this is true whether you get Democrats or Republicans in the office, you have them moving back and forth through the revolving door, and in a way, our government is invisible a lot of the time as it's policies are carried out by a corporation on one level or another, and then again, the policies of the government are basically forged by the Corporatocracy and then presented to the government and become government policies. So, it is an incredibly cosy relationship. This isn't a "conspiracy theory" kind of thing, these people don't have to get together and plot to do things, they all basically work under one primary assumption, and that is that they must maximise profits regardless of the social and environmental costs.

This process of manipulation by the Corporatocracy, through the use of debt, bribery and political overthrow, is called "Globalisation". Just as the Federal Reserve keeps the American people in a position of indentured

servitude, through perpetual debt, inflation and interest, the World Bank and International Monetary Fund fulfil this role on a global scale.

Oh, and by the way, the lame excuse for going to war with Iraq which was never believable beforehand, is laid out in fair detail here by a high-ranking US Major General expert in gathering and interpreting military and terrorist intelligence: http://www.youtube.com/watch?v=W0xzsbSbVUE&feature=player_embedded.

Libya 2011: If the ruler of a country refuses to become the servant of the New World Order people, he is subjected to character assassination and physically attacked with troops. I don't for a moment suggest that Col. Gaddafi was a saint, but as the Bible so aptly remarks, you can tell a man's character by the things which he does, so what did Col. Gaddafi do? Well, here is some information passed to me and I leave you to decide for yourself:

1. In Libya, electricity is free for all of its citizens.
2. There is no interest on loans, banks in Libya are state-owned and loans are given to all its citizens at 0% interest which is requirement of Libyan law.
3. Owning a home is considered a human right in Libya – Gaddafi vowed that his parents would not get a house until everyone else in Libya had a home. Gaddafi's father has died while he, his wife and his mother were still living in a tent.
4. All newlyweds in Libya receive \$60,000 Dinar (US\$50,000) from the government, to buy their first apartment to help them start a family.
5. Education and medical treatments are free in Libya. Before Gaddafi only 25% of Libyans were literate. Today the figure is 83%.
6. If any Libyan wants to take up farming, he receives farming land, a farm house, equipment, seeds and livestock to kick- start their farms – all for free.
7. If Libyans cannot find the education or medical facilities they need in Libya, the government funds them to go abroad for it – not just free, but they get US\$2, 300 per month for accommodation and running a car.
8. If a Libyan buys a car, the government pays 50% of the price.
9. The price of petrol in Libya is US\$0.14 per litre (in the UK, it is \$2.17 per litre at this time, which is more than 15 times as much).
10. Libya has no external debt and its reserves amount to US\$150 billion – now frozen globally.
11. If a Libyan is unable to get employment after graduation, the state pays the average salary of the profession as if he or she is employed, until employment is found.
12. A portion of Libyan oil sale revenues is credited directly to the bank accounts of all Libyan citizens.
13. A mother who gives birth to a child receives US\$5 ,000.

14. 40 loaves of bread in Libya costs just US\$ 0.15 (in the UK, it is 200 times more expensive).
15. 25% of Libyans have a university degree, while in the UK, Sir Clive Woodhead, former Chief Inspector of Schools, has recently recommended that children should leave school at age 14 and become apprentices.
16. Col. Gaddafi carried out the world's largest irrigation project, known as the Great Man-Made River project, to make water readily available throughout his desert country.

So, I will leave it up to you to decide if the attacks on Libya and the killing of Col. Gaddafi was an honest action designed to make the world a safer and better place, or if those actions were motivated by some other agenda.

The Technique:

The lawyers and bankers have the objective of taking all of your money and keeping you permanently in debt to them. In the UK, the currency was "the pound sterling" and a £1 note was a promise certifying that there was literally a one pound weight of sterling silver held in storage to back the value of that note and save the person carrying around the actual pound weight of silver.

That link was broken, and nowadays, the £1 note (or in the US, the \$1 note) has no actual value as it is no longer a promise that an amount of valuable metal is being held in storage in order to give that piece of paper its value. In reality, these paper currency notes have no more value than the paper notes in the board game "Monopoly" and that value is only the value of the paper on which the notes are physically printed, which is, almost nothing at all.

Take the process in America as an example: The "government" decides that it needs some money, so it calls up the (privately owned) Federal Reserve Bank and requests, say, \$10,000,000,000. The Federal Reserve Bank replies saying "Sure, we will buy \$10 billion in government Bonds from you". So the "government" takes some pieces of paper, paints some official-looking designs on them and calls them "Treasury Bonds". Then it puts a value on them of \$10 billion and sends them over to the Federal Reserve Bank. In turn, the people in the Federal Reserve Bank draw up a series of impressive looking pieces of paper themselves, only, this time, calling them Federal Reserve notes, also designated with a value of \$10 billion. The Federal Reserve Bank then takes these notes and trades them for the Treasury Bonds. Once this trade is complete, the government then takes the \$10 billion in Federal Reserve notes and deposits them in a bank account, and on doing this, the \$10 billion becomes legal tender money, adding \$10 billion to the US money supply. And there it is: \$10 billion in new money has been created out of nothing and with no intrinsic value whatsoever. Of course, this example is a generalisation because in reality, this transaction would occur electronically, with no paper used at all. In fact, only 3% of the US money supply exists in physical currency and the other 97% exists in computers alone.

The same style of operation happens in the UK as well with the (privately owned) Bank of England, producing valueless 'currency'. The banks deliberately compound the problem by lending this valueless money to individual people as a loan or mortgage, knowing full well that there is not enough money in circulation to pay off the loan and the interest. If, for example, the loan is £1000 on a credit card, then the credit card company will want about £1200 back as they charge interest. But as they do that with all of the "money" fraudulently created (actually ten times the amount in America), there is physically not enough to allow the interest to be paid unless the economy of the country keeps on expanding rapidly. The objective here is to take physical goods and possessions away from the borrower when he finds himself unable to pay the amount asked for.

The total lack of value of present day currency was demonstrated when a mortgage loan repossession was challenged in court in America. For any commercial contract anywhere in the world to be valid, something of worth has to be put forward by both parties to that contract. When a bank "lends" its worthless money as a mortgage, it has put forward nothing of value and so the mortgage contract is not valid in law.

In 1969, there was a Minnesota court case involving a man named Jerome Daly who was challenging the foreclosure of his home by the bank which provided the loan to purchase it. His argument was that the mortgage contract required both parties (himself and the bank) to put up a legitimate form of property for the exchange. In legal language, this is called a "consideration" from both parties. Mr Daly explained that the money was, in fact, not the property of the bank as it was created out of nothing as soon as the loan agreement was signed. In other words, the money didn't come out of the bank's existing assets as the bank simply invented it, consequently, the bank put up nothing of value of its own, except for a theoretical liability on paper. As the court case progressed, the bank's President, Mr Morgan, took the stand and the judges memorandum records that the "Plaintiff admitted that it, in combination with the Federal Reserve Bank ... did create the entire \$14,000 in money in credit upon its own books by bookkeeping entry ... the money and credit first came into existence when they created it. Mr Morgan admitted that no United States Law or Statute existed which gave him the right to do this. A lawful

consideration must exist and must be tendered to support the Note" ... The jury found that there was no lawful consideration, and on this finding, the court rejected the bank's application for foreclosure and Mr Daly kept his home.

The Consequences:

There does not seem to be much point in commenting on the situation in other countries around the world as you will find the same style of underhand operation in most of them. However, when you understand what is going on, it explains why it has been so difficult to get any free-energy device on to the market for sale to members of the public.

A really major strand of both income and control comes from access to energy. The average person wants energy for heating and cooling a home, running household equipment such as refrigeration, lighting, computing, etc. and for powering a vehicle, operating power tools, and so on. Under the present deceptive regime, we are told from an early age that we need to burn a fuel in order to get this power, and instead of doing it individually, it appears to be cheaper to buy the power from the local energy company.

The reality is that we live in a sea of energy which can supply our every need for ever and ever without the slightest need for burning any kind of fuel. Devices for tapping this energy have been produced by literally thousands of inventive people and yet, they are not for sale. Why do you think that is?

Well, one of the reasons is that inventors of these devices often feel that they should "protect" their invention by patenting it and so they make an application to a Patent Office. Unfortunately, the Patent Office is a commercial business owned by the same people who make massive amounts of money from selling you oil to burn and electricity to use. Because of that, they steal the best of these inventions, often by telling the inventor that his invention is "Of National Security Importance" and so he can't use it, sell it or even speak to other people about it, and if he did, he would be put in prison. That is, of course, an unlawful deception as the people telling him that have nothing whatsoever to do with anything National, except the use of the word in their company name. There certainly is no government around to make any kind of statement like that.

The wonderful people then use your money in unlimited amounts to develop these inventions as secret "black" projects and they have been doing this for at least a hundred years. People who have been employed in some of these projects report that they now have technology anything from 100 to 1,000 years in advance of what the public is told about. Almost everything shown in the fictional "Star Trek" series has already been produced covertly in real life. The internet has made it difficult to keep on hiding these advances, but they fight back by posting false information, contradicting people who present the real deal, and generally disrupting and flooding every useful forum with a combination of rubbish and inflammatory attacks on forum members.

A major strand of the attempt to suppress the truth is through universities and respected Engineering bodies and publications. This is done through financial pressure. To have a successful career, a university professor needs to have regular publication of research papers. For this, he needs researchers who are paid to do the research. This is done through grants from rich people and organisations. Those are the very people who will under no circumstances allow the publication of any research which demonstrates that free-energy exists and they make sure that no funding will ever be available for any such research.

If a scientist steps out of line and goes public with the facts, he is immediately attacked by all of his former colleagues who promptly say that what he says is "impossible" and "breaks the laws of physics", neither of which are actually true. For example, in 2010, Rosemary Ainslie and her colleagues demonstrated under strict laboratory conditions that a pulsed heating element produces 17 times more heat output than could be produced by the tiny electrical input driving the element. This was written up in standard scientific paper format and passed to the Institute of Electrical Engineers for examination and publication. As was expected, the paper was refused in spite of the fact (or perhaps because of the fact) that the laboratory results were conclusive. None of the present scientific institutions will publish any form of free-energy paper as that would not be good for the business of their owners.

If an inventor skips the Patent Office, avoids the scientific journals, and tries to get his invention manufactured, he needs substantial funding and that is usually blocked by the concerted efforts of the groups of companies whose businesses would be harmed by the invention becoming freely available to the public. Some times, the inventor is threatened and intimidated. I personally know several people who have had this done to them, but the most common block is financial. For example, Cal-Tech in America spent a million dollars developing, testing, proving and perfecting a carburettor which gave vastly improved mpg results and which cut pollution to near zero. They teamed up with the very large auto-parts supplier Arvin Meritor to put the carburettor into production vehicles. Then "One Equity Partners" bought out the Arvin Meritor division which did all the final work, and then they created a new company, "EMCON Technologies", which dropped the carburettor from their product line, not

because it did not work but because it did work. Oil sales were the only interest and cutting pollution was seen as irrelevant.

The Practical Situation

Some of this is quite difficult to absorb and understand, so perhaps a little extra detail may be helpful. Just to recap; there are two separate and totally different systems: the law and the legal system.

The law boils down to “don’t harm anyone or his property, steal his property or swindle him”. That is pretty straightforward and it is binding on everyone. You will notice that it does not say anything about keeping to a speed limit, paying taxes, getting married, serving in an army, voting in an election, or any one of thousands of other things. Those things are not required by the law. The requirements of the law are “don’t harm anyone, damage or steal his property or defraud him”, nothing else.

The legal system is an invention intended to do exactly the opposite, namely, harm you, steal your property, subject you to the will of someone else and to defraud you generally. The operating method is lies and deception and a prolonged attempt to prevent you finding out the facts. Thankfully, being subject to the legal system is optional – completely your own choice. So, by refusing to consent to being subject to it, you can shrug it off and live a life free from it.

One of the really difficult things to understand is finance. For example: Al Baker, decides to set up a finance company, lending money and charging interest on the loans. He registers “The Swindle Finance Company Limited”, which is a paper invention of the legal system and is not actually a real thing at all – just some pieces of paper and a name written into a list of paper companies.

His friend Charles Daly who lives across the street, decides to deposit £10,000 (or dollars, or Euros, or whatever the local currency is called) with Al because Al is offering 10% annual interest on all deposits as a special advertising promotion. Al puts the money in the bank account of Swindle Finance Company Limited and enters the amount as a credit in the company accounts ledger. Big smile – the business is starting to roll in.

Gary Hughes then decides that he could do with a round-the-world holiday cruise and so he asks Al for a loan of £10,000. Al is delighted and is about to lend him the £10,000 which Charles lodged when his financial director, Ed Foyle, says “hey, you can’t do that, there is a (statute) law against it - if Charles suddenly need money for something and wants to withdraw his money, you have to be able to repay him in full, so you are not allowed to lend his money to anyone else”.

Al is a bit stumped by that and asks “how can we lend money then – it seems impossible?”. It’s quite ok says Ed, we just invent the money. Here, get Gary Hughes to sign this form, but make quite sure that the form says “Mr Gary Hughes” or “MR GARY HUGHES” as that is very important. When the form is signed, we can enter it in our company accounts as a credit because his signature makes it a promissory note which has a value of £10,000 for us. Then, we start making real money by writing him a cheque instead of handing him money. He will sign that cheque in order to cash it and that is worth another £10,000 to us. This is great business as we can enter his signed cheque into our ledger as another £10,000 asset, and write the £10,000 which goes into his account as a debit. We have now got £20,000 coming in and only £10,000 going out, so we are already ahead by £10,000 and it isn’t even time for lunch on our first day. Also, if Gary pays back the loan and our 20% interest, then this transaction will have made us a net profit of £22,000. If he didn’t pay us back anything, we would still be £10,000 ahead, so let’s celebrate.

Poor Al is a bit confused, so he asks “but where does the £10,000 that we lend Patrick come from?”. Ed laughs and says, it doesn’t come from anywhere, we just write numbers into our ledger against the name of Mr Gary Hughes – it doesn’t cost us anything – do you think he would hold still long enough for us to stamp “sucker” on his forehead? After all, he is about to pay us more than twice, which means that we will make millions in profit each year. Poor Al is still confused, which is a pity, as Gary is the only person which Ed wants to keep confused about the transaction.

Ed knows all of the legal angles and when he is driving home he exceeds the speed limit. It is not dangerous in any way as there is no other traffic, and the road conditions are perfect. A police car pulls alongside him and indicates that they want him to stop, so he pulls over and stops. A police officer approaches and asks Ed if he is aware that he was driving at 40 mph in a 30 mph zone. Ed says that he was indeed aware of that.

The police officer then asks Ed for his name and address. But, Ed is aware of the fact that this is a fraudulent attempt to get him to agree to “Joinder”, that is, agreeing that he is subject to all legal statutes, giving the police officer authority over him. So, he promptly states that the law does not require him to provide any such information, he also mentions the fact that the law does not require him to drive at, or below, 30 mph in a 30 mph zone. The police officer tries this again several times, getting the same answer each time.

Being a bit stumped by this unexpected response, the police officer switches tactics and says that he may have to take Ed down to the police station for further questioning and asks if Ed understands. Being well up on legal

tactics and realising that asking “do you understand” is a fraudulent attempt to establish Joinder, he calmly states that under the law, he is not required to go to a police station and he does NOT “stand under” the police officer or his statement. He also remarks that if he is taken to a police station unlawfully and against his will and without his consent, then he will take action against the police officer personally as a man and not as a police officer, for his unlawful actions. He also asks the police officer if he is aware that the Police Authority which employs him is not a government agency but is a commercial for-profit company with no powers whatsoever to uphold the law, that the police officer is only empowered to uphold the law through the oath which he personally took when he became a policeman and it has nothing whatsoever to do with any form of authority coming from his employers. In other words, he is on his own on this one.

Ed further points out that under the law, there has to be a victim (who has been injured, has his goods damaged or stolen, or who has been defrauded) and he asks the police officer to identify the victim in this case. He also remarks that legal statutes only have the force of law for those people who consent to be bound by them, and he does NOT consent to be bound by them, and so, driving at 40 mph in a 30 mph zone where nobody was endangered and no harm or damage occurred, is not an offence for him.

I'll leave you to work out the likely outcome of the conversation between Ed and the police officer.

Six months later, Ivan Johnson, a friend of Gary Hughes, remarks that Gary is looking worried and asks him if anything is wrong. Gary, who is self-employed, says that business has been very poor for some time and he is having financial problems. His main difficulty is this loan that he has with the Swindle Finance Company Limited. He has not been able to keep up the payments and he has just had a letter from them saying that he has to pay £2,231.47 by Friday, or they will take him to court. Fortunately, Ivan is familiar with both finance and legal matters, so he tells Gary what to do. His advice is simple, he says; for your contract with the Swindle Finance Company Limited to be valid, it has to meet these requirements:

1. Full disclosure, which didn't happen as they did not tell you that your signature created the credit.
2. Equal Consideration, which didn't happen as they have nothing to lose as they didn't bring anything to the table.
3. Lawful terms and conditions
4. Signatures of the Parties, which didn't happen as companies can't produce a “wet ink” signature.

So, you send them a letter agreeing to pay any financial obligation which you might lawfully owe, as soon as they:

1. Provide validation of the debt, that is, the actual accounting.
2. Verification of their claim against you, that is, a sworn affidavit or a signed Invoice.
3. A copy of the Contract binding both parties.

Sign the Letter “Gary Hughes” (**not** “Mr Gary Hughes”) and write “All Rights Reserved” after your signature. Send the letter by registered delivery so that there is a third-party record of it being delivered to them.

The financial institution can't validate the debt as they never sustained a loss. They can't verify any claim against you as their billing is to “Mr Gary Hughes” or “MR GARY HUGHES” or “Mr G. Hughes” or “Hughes, Mr G” or some such wording, and none of those is you, since you are the man Gary Hughes. They can't produce a copy of the contract, because one doesn't exist – what exists is an unenforceable unilateral contract with no standing in law.

If they send you a statement of account, then tell them that a statement is not an Invoice and that you need an Invoice. If they send you a photocopy of your loan application form, then tell them that it is not a contract, being signed by only one of the parties.

If they delay and delay, then write and tell them that if they do not provide the requested documentation within fourteen days, that you will consider any debt as being fully discharged.

If they are ill-advised enough to attempt to take you to court, send a copy of your letter agreeing to pay provided they produce the evidence that there is something outstanding to pay, to the court. They may well be penalised by the court for wasting court time as courts only adjudicate between parties who disagree and there is no disagreement in your case as you have agreed to pay if the Swindle Finance Company Limited shows you that you are liable to pay them some amount of other.

Having had this explained to him, I will leave it up to you to decide if Gary felt any better about his situation.

The legal system is very large and very complex. This is quite deliberate and it is intended to make sure that no ordinary person knows all of it. Fortunately, the law is much less complicated and if you are very careful not to walk into any of the traps set for you, you can effectively ignore the legal system. If required to sign anything and you decide to do so, then Gary Hughes should sign it “By: Gary Hughes, agent” or “By: Gary Hughes, principal” as that you are not taking on any responsibilities in the strawman's name.

John Harris of the TPUC organisation, has found a very effective technique for dealing with the attempts of the legal people to extract money from you, is to never go to court (remember that a 'Summons' is only an invitation and you can decline it) and returning all correspondence marking it "No Contract – Return to Sender". This avoid you ever walking into a "Joinder" trap and becoming liable for the fraudulent claims being made against your strawman. I suggest that you research this subject further and become completely familiar with your rights under common law, and the fraudulent "Joinder" traps being set for you. What you decide to do after that, is entirely up to you.

The Situation in Australia

It appears that both the government and the legal system of Australia are null and void as the basis on which they were created no longer exists. Sir Harry Gibb has this to say about the situation:

I am a former member of the High Court and I wish to take this unusual method of informing you about a matter that is going to deeply affect us all. Unfortunately, a document such as this is too easily "lost" in the bureaucratic jungle in which we operate.

A group of Australian Citizens have taken it upon themselves to test the validity of our current political and judicial system. Like you, I have lived my entire legal career with the assumption that the basis for our legal and political system, state and federal, was written in stone. This group has undertaken to present this paper where they test the legal system.

The group is articulate, well educated and has some of our best legal minds amongst its members. One of Australia's best known barristers is one of the group's leading lights. It is far better informed with regard to international law than most members of the judiciary or for that matter, the legal academe. It has better international contacts than I would have thought possible.

After spending some time with the group leader, I was able to elicit it's primary intentions. It is the introduction of a totally democratic system of government devoid of party politics operated by the will of the people incorporating a system of debit taxation which should go a long way to eliminating the current unemployment problem and addressing other pressing social issues. An A.B.S. financial model supports the proposal.

The group has so far concentrated on matters relating to taxation, state and federal, minor industrial and motor traffic while undertaking not to present a criminal defence using their current presentation. I challenged the leader of this group to present any evidence which he had with regard to the above defence so that I could use my legal expertise to play the part of devil's advocate. It should be brought to your attention that the group has access to documentation of which we members of the judiciary have little knowledge. I refer to the British Parliamentary Papers for the Colony of Australia for the years 1860 through to 1922.

These are photocopies of all documents correspondence etc., between the states and later the Commonwealth of Australia, the British Crown and the British Government. They are very revealing documents and indicate the degree of chicanery in which the politicians of all shades were involved and as I can now see, at the expense of the legal academe and the judiciary. I present for your perusal the details of the group's presentation along with my comment on each major item. The group relies solely upon historical fact and rejects political rhetoric and legal opinion unless based upon historical fact.

1. "The Commonwealth of Australia Constitution Act 1900 (UK) is an act of the parliament of the United Kingdom. It did not contain any substance of sovereignty and was a colonial act centralising self-government of the six Australian Colonies. Australia remained a colony of the United Kingdom."
 - 1a. Although the late Lionel Murphy attempted to show that there was an element of sovereignty in this act, he failed to do so. The international definition of sovereignty has been espoused at length and the above act although important in the development of Australia, did not have the authority of sovereignty. The historical evidence that Australia remained a British Colony post 1901 is overwhelming.
2. "Australia made an international declaration of its intention to become a sovereign nation when Prime Minister Hughes and his deputy; Sir Joseph Cook signed the Treaty of Versailles on June 28, 1919. On its cognisance of signing this treaty, Australia was granted a "C" class League of Nations mandate over former German territories in the Pacific. In effect, Papua New Guinea became a colony of Australia achieving its own independence on 16 September 1975. The League of Nations became part of International Law on 10 January 1920 with Article X of the Covenant of League of Nations guaranteeing the sovereignty of each member."
- 2A. The Significance of Australia joining the League of Nations as a foundation member has never been

addressed in Australia before. Strangely, only one book has ever examined the question of Australian independence. Written by W. J. Hudson and M. P. Sharp in 1988 "Australian Independence" printed by Melbourne University Press. As both were members of the Department of Foreign Affairs and Trade at the time of authorship and had access to the, British Parliamentary Papers, I find it most interesting they have avoided any mention of these papers in their book. Their conclusion that Australia became an independent nation via. the Statute of Westminster in 1931 flies in the face of contradictory evidence within the above mentioned papers and readily available historical fact.

Prime Minister Hughes address to the Commonwealth Parliament on 10 September 1919, "Australia has now entered into a family of nations on a footing of equality. Australia has been born in a blood sacrifice" demonstrates that the politicians of the day were only too well aware of the change of status from a colony to that of a sovereign nation, while attempting to remain within the Empire.

Prime Minister Bruce made this reply to the British Government in 1922 after a request for troops against Kernel Ataturk in the Chanak crisis. Bruce's reply is contained in the British Parliamentary Papers: "We have to try to ensure there shall be an Empire foreign policy which if we are to be in anyway responsible for it, must be one to which we agree and to which we have assented. If we are to take any responsibility for the Empire's foreign policy, then there must be a better system, so that we may be consulted and have a better opportunity to express the views of the people of this country. We cannot blindly submit to any policy which may involve us in war." This is a far cry from the declaration of war against Germany made on behalf of the British Colony of Australia by George V of the United Kingdom in 1914.

I have reproduced Bruce's reply in full as I believe this reply contains clear historical evidence of a Prime Minister who was well aware of the change of status from a colony to a sovereign nation. The later Statute of Westminster 1931 was an acknowledgment of that status.

3. "Paragraph 4 of the Statute of Westminster Act 1931 contravenes Article X of the Covenant of the League of Nations. Paragraph 1 of the Australia Act 1986 contravenes Article 2 paragraphs 1 and 4 of the Charter of the United Nations."

3A Paragraph 4 of the Statute of Westminster reads "No Act of Parliament of the United Kingdom, passed after the commencement of this Act, shall extend, or be deemed to extend, to a Dominion as part of the law of that Dominion, unless it is expressly declared in that Act, that the Dominion, has requested, and consented to the enactment thereof." Paragraph 1 of the Australia Act is very similar: "No Act of the Parliament of the United Kingdom passed after the commencement of this Act shall extend, or be deemed to extend, to the Commonwealth, to a State or Territory as part of the law of the Commonwealth, of the State or of the Territory."

I passed this one to the Federal Attorney General and asked him what was the source of this quite incredible authority that sought to overturn the authority legislated within the Covenant of the League of Nations in Article X and the Charter of the United Nations in Article 2 paragraphs 1 and 4. He is unable to provide any documentation to support these clauses, Article X of the Covenant of the League of Nations states: "The members of the League undertake to respect and preserve against external aggression the territorial integrity and existing political independence of all Members of the League. In case of any such aggression or in case of any threat or danger of such aggression, the Council shall advise upon the means by which this obligation shall be fulfilled."

It is appropriate that I now introduce a statement by Sir Geoffrey Butler KBE, MA and Fellow, Librarian and Lecturer in International Law and Diplomacy of Corpus Christi College, Cambridge author of "A Handbook to the League of Nations" used as a reference to the League by virtually all nations at that time. He refers to Article 1 of the Covenant of the League of Nations:

"It is arguable that this article is the Covenant's most significant single measure. By it the British Dominions, namely New Zealand, Australia, South Africa, and Canada, have their independent nationhood established for the first time. There may be friction over small matters in giving effect to this internationally acknowledged fact but the Dominions will always look to the League of Nations Covenant as their Declaration of Independence.

Article 2 paragraph 1 of the United Nations Charter states "The Organisation is based on the principle of the sovereign equality of all of its Members."

Article 2 paragraph 4 of the Charter states 'All members shall refrain in their international relations, from the threat or use of force against the territorial integrity or political independence of any state, or in any other manner inconsistent with the Purposes of the United Nations."

In view of the above, the historical evidence for Australian Independence by 10 January 1920 when the League of Nations became part of International Law is overwhelming. When this evidence is reinforced with the contents of

the Charter of the United Nations, the continued usage of any legislation that owes its very legitimacy to the parliament of an acknowledged foreign power cannot be supported by either legal opinion or indeed historical evidence.

I therefore have come to the conclusion that the current legal and political system in use in Australia and its States and Territories has no basis in law.

Following discussions with members of the British Government relating to the Letters Patent for the Governor General and State Governors I find that these documents no longer have any authority. Indeed, the Queen of the United Kingdom is excluded from any position of power in Australia by the United Nations Charter and is excluded under UK law from the issue of a Letters Patent to other than a British Subject. A Letters Patent must refer to an action to be taken with regard to British Citizens. In the Immigration Act 1972, the UK defines Australian Citizens as "aliens".

The Governor General's Letters Patent is a comedy of errors. We are greeted in the name of the Queen of Australia who suddenly becomes the Queen of the United Kingdom in the next paragraph of the Letters Patent. This Queen then gives instructions to the Governor General with reference to the Commonwealth of Australia Constitution Act 1900 UK. Here we have a clear breach of Article 2 paragraph 1 of the United Nation Charter. Under both UK and international law, the-Queen is a British Citizen.

State Governors are in a worse position since their authority comes from the late Queen Victoria of the United Kingdom. Regardless of the validity of the Commonwealth of Australia Constitution Act 1900 UK, if the authority of Governor General and the State Governors is invalid then so is the entire political and legal system of government.

When advised that the War Crimes Commission was taking an interest, I called them in Geneva. Under the 1947 Geneva Convention, they are empowered to look into cases here in Australia where it is alleged that the law of a foreign country was enforced against a citizen of a member state of the United Nations. As they perceive that only the judiciary can actually enforce the law, the judiciary becomes their target. The group has already placed cases before them which they are currently investigating. If found guilty, the penalties are horrific and include the death penalty!

I could go on with more relevant information however I think now is the time for a summary. The group leader, a QC, states the obvious when he asked me how could a colony now acknowledged by all world nations to be a sovereign Nation, retain exactly the same legal and political system which it enjoyed as a colony, without any change whatsoever to the basis for law. This point alone requires an answer.

The High Court has already answered with regard to the position held by treaties signed by the Commonwealth Government in the Teoh case of 1994. "Ordinary people have the right to expect government officials to consider Australia's international obligations even if those obligations are not reflected in specific Acts of Parliament: the rights recognised in international treaties are an implied limit on executive processes."

My advice is to adjourn any case "sine die" that challenges the authority of the Letters Patent. Under no circumstances hear a case that challenges the validity of a State or the Federal Constitution. It is the politicians who are using us as pawns without them having to face the music. If these matters are of concern to politicians, then let them sort out these problems and accept any inherent risks themselves! Article 36 of the Statute of the International Court of Justice is the correct reference for you to refuse to hear a matter when an international treaty is cited as a defence.

The Comments of Brian Collins

The following is some of what the very knowledgeable Brian Collins has to say on his web site. I merely quote what he says here and I have not verified any of this material, and so I recommend that you check out these things for yourself.

The Greatest Lie Ever Told

The government and legal system of the United States, Canada, Australia, New Zealand and of course, Britain, is totally controlled by the Crown. The Crown is **not** the British Monarch. The Crown is the Inner City of London, which is an independent State in London belonging to the Vatican system. It is a banking cartel which has a

massive system around and beneath it, which hides its true power. The City is in fact, the Knights Templar Church, also known as the 'Crown Temple' or 'Crown Templar', and is located between Fleet Street and Victoria Embankment. The Temple grounds are also home to the Crown Offices at Crown Office Row.

The Crown Temple controls the Global 'Legal' system, including those in the United States, Canada, Australia, and much more; this is because all Bar Associations are franchises of the International Bar Association at the Inns of Court at Crown Temple based at Chancery Lane in London. All Bar Associations are franchises of the Crown and all Bar Attorneys/ Barristers throughout the world pledge a solemn oath to the Temple, even though many may not be aware that this is what they are doing. Bar Association 'licensed' Solicitors / Barristers must keep to their Oath, Pledge and terms of allegiance to the Crown Temple if they are to be "called to the Bar" and work in the legal profession. The ruling Monarch is also subordinate to the Crown Temple, this as been so since the reign of King John in the 13th century when Royal Sovereignty was transferred to the Crown Temple and, through this, to the Roman Church. King John 1167-1216 is the key to this deception.

It was at the Chancel, or Chancery, of the Crown Inner Temple Court in January 1215 that King John was faced with the demands of the French/English Barons in England (mainly French), to confirm the rights enshrined in the Magna Carta. When he signed the Magna Carta in 1215 history records this as an event that extended human freedom, but the real affect was very different as we shall see. The governments of the USA, Canada, Australia and more, are subsidiaries of the Crown Temple and so is the US Central Bank the Federal Reserve, as are all Central Banks on the planet, including the IMF World Bank.

Bar Associations are awarded their franchises by the Four Inns of Court at Temple Bar. These are the Inner Temple, Middle Temple, Lincolns Inn and Greys Inn and they are nothing less than elite secret societies without charters or statutes. They are the law unto themselves. The Inner Temple controls the legal system franchise for Canada and Britain while the Middle Temple does the same for the United States. Queen Elizabeth II is a member of both Temples. At least five signatories to the American Declaration of Independence were Temple Bar Attorneys who had pledged allegiance to the Crown! Another Middle Temple operative during the formation of the USA was Alexander Hamilton who structured the American Banking system to fulfil the Crown Temples agenda for total control of the United States. So in truth, a State wherever it is on this planet, is a legal entity of the Temple Crown, or a Crown Colony. A man named Michael Edwards wrote:

"Americans were fooled into believing that the legal Crown Colonies comprising New England, were independent nation states, but they never were, nor are they today. They were, and still are, Colonies of the Crown Temple, through letters patent and charters, who have no legal authority to be independent from the rule and order of the Crown Temple. A legal state is a Crown Temple Colony".

"Neither the American people nor the monarch of Britain own America. The Crown Temple owns America through the deception of those who have sworn their allegiance by oath to the Middle Temple Bar. The Crown Bankers and their Middle Templar Attorneys rule America through unlawful contracts, unlawful Taxes, and contract documents of false equity through debt deceit, all strictly enforced by their completely unlawful, but 'legal', orders, rules and codes of the Crown Temple Courts, or the so called, 'Judiciary', in America. This is because the Crown Temple holds the land titles and estate deeds to all of North America".

Seven Middle Inn Templars who had pledged an oath of allegiance to the Crown Temple (including Alexander Hamilton) were among the members of the Constitutional Convention who signed the completed 'American Constitution'. How symbolic it is that copies of the American Constitution and the Declaration of Independence hang on the wall of the Middle Temple in London. It's not that surprising when you consider that this Temple controlled both sides in these shenanigans.

So while the Middle Bar Templars were orchestrating the illusion of freedom from the perceived rule by King George III, the King too, was a sworn member of the same Temple. Michael Edwards continues:

"1776 is the year that will truly live in infamy for all Americans. It is the year that the Crown Colonies became legal Crown States. The Declaration of Independence was a legal, not lawful, document. It was signed on both sides by representatives of the Crown Temple. Legally, it announced the status quo of the Crown Colonies to that of the new legal name called 'States' as directly possessed estates of the Crown.

"The American people were hoodwinked into thinking that they were declaring lawful independence from the Crown. The proof that the colonies are still a Crown possession is the use of the word 'State' to signify a 'legal estate of possession'. Had this been a document "of and by the people", then both the Declaration of Independence and the US Constitution would have been written using the word 'States'. By the use of 'State', the significance of government of estate possessions was legally established. All of the North American States are Crown Templar possessions through their legal document, signed by their representation of both parties to the contract, known as the Constitution of the United States of America.

Who controls the Crown? On 15th May 1213, King John, being a puppet of the Knights Templar, effectively signed away the Kingdom of England and Ireland to Pope Innocent III and the Roman Church, witnessed by the Crown Templars. As King John said at the time: "I myself bearing witness in the house of the Knights Templars".

The King John Charter said:

" We wish it to be known to all of you, through this our charter, furnished with our seal... not induced by force or compelled by fear, but of our own good and spontaneous will and by common counsel of our Barons, do offer and freely concede to God and his Holy Apostles Peter and Paul and to our mother the holy Roman Church, and to our lord Pope Innocent and to his Catholic successors, the whole kingdom of England and the whole kingdom of Ireland, with all their rights and appurtenances... we perform and swear fealty for them to him are aforesaid lord pope Innocent, and his Catholic successors and the Roman Church...

binding our successors and our heirs by our wife forever, in a similar manner to perform fealty and show homage to him who shall be chief pontiff at the time, and to the Roman church without demur. As a sign... we will and establish perpetual obligation and concession... from the proper and especial revenues of our aforesaid kingdoms...

the Roman church shall receive yearly a thousand marks sterling... saving to us and to our heirs our rights, liberties and regalia; all of which things, as they have been described above, we wish to have perpetually valid and firm; and we bind ourselves and our successors not to act counter to them. And if we or any of our successors shall presume to attempt this, whoever he be, unless being duly warned he come to his kingdom, and his senses, he shall lose his right to the kingdom, and this charter of our obligation and concession shall always remain firm."

Now it gets interesting. Historical accounts concentrate on the fact that this charter obliged the Crown to pay money to the Roman Church, but it also states that if the terms of the charter are broken, the 'right to the kingdom' shall be lost. When King John signed the Magna Carter on 15th June 1215, he broke the terms of the charter with the Pope and therefore lost the right to his Kingdom. Pope Innocent III then declared the Magna Carter to be null and void. From that time, the 'Crown' passed from the Monarch to the Knights Templar who to this day, govern Britain on behalf of the Roman Illuminati Church.

The St Clair's now Sinclair are the initial directors of this link of Templar and Rome in the British Isles as they took hold in Scotland at the time of the 1066 Norsemen-Norman invasion. This means that ultimately, through the Crown Temple, the Roman system also owns the United States, Canada and all countries and Bar associations controlled both overtly and covertly by the Crown. This is why the Peace Treaty between the American Colonies and the British Crown in 1783, stated:

"It having pleased the Divine Providence to dispose the hearts of the most serene and most potent Prince George the third, by the grace of God, King of Great Britain, France and Ireland, defender of the faith, Duke of Brunswick and Luneburg, arch treasurer and prince elector of the Holy Roman Empire etc... and of the United States of America..."

And ironically, a Roman Catholic is barred from being the British Monarch while all along the Monarch and the Kingdom have been owned by the system that is Rome.

The Queen is the Grand Patroness of Freemasonry. She is served by the 390 members of the Privy Council which connects with it's equivalent in all other Commonwealth Countries. The Privy Council is 'LEGALLY' above Parliament because of its prerogative powers. It's members, are appointed for life and they include Prince Philip, Prince Charles, the Archbishop of Canterbury, the Prime Minister and many others. They hold nine official meetings each year and the government (Crown) minister's stand to attention while the Queen is told of the government measures they are asking the Queen to approve, which are nothing other than what the Crown dictates via the elected leader and via the Whips of whichever political party has power... After taking their bow to the Queen and shaking her hand they are sworn to conduct their business in the utmost secrecy.

Another network of this structure is the CROWN AGENTS. Formed in 1833 as 'Crown Agents for the Colonies', to run the day to day administration of the empire and to serve as private bankers to government officials, colonial authorities, and heads of state. It is also an older version of Brown & Root supplying a vast range of goods throughout the empire. Goods that included arms, drugs, viruses, especially to Africa to create the genocidal wars we are now witnessing and have witnessed in the past. The 'Crown Agents' is the network which links the Crown Temple to the organised crime operations throughout the empire, the Golden Dawn being one of the most powerful occult operations to be used in Britain amongst the crime syndicates to ensure that the right crime waves are in full swing when required.

We can see this in the current agenda for guns. The Golden Dawn also operates within legal organisations, but is the interconnecting network across all secret societies and religion. Remember that the Crown Agents work

directly for the Monarch who works for the Knights Templar Church, which operates for the Vatican, and to add insult to injury, the entire debt of the Crown Agents is guaranteed by the British Government, and that means you!

In the 1970's it was bailed out by the Bank of England costing hundreds of millions of pounds. For many years the Crown Agents managed the personal wealth of the Sultan of Brunei who just happens to be a great friend of the Queen, and who has funded many of Prince Philip's, Prince Charles', and George Bush senior's private projects. The Sultan is also the financier of both the British and the American unofficial intelligence operations as he has backed many of Mohammed Al Fayed's operations, in fact the Sultan could be said to be Mohammed Al Fayed!

After the murder of Princess Diana, the role of Al Fayed was for him to hijack the conspiracy and thus lead investigators down the Al Fayed rap of misinformation as was done with Nick Brown over the top-up fees debate, and is currently being played by David Davis. Fortunately no one needed to go to him for information because we all in our hearts already know that she was murdered.

In 1996 the 'Crown Agents' operation was privatised and given the name 'Crown Agents for Overseas Government and Administration Ltd'. Of course, privatisation is nothing but transfer of Power from Crown Temple through Government agency to Crown Temple via direct ownership: they own everything in this nation!

Just to give an idea of What the Crown Agencies controls, here are a few little companies which it controls. It acts as a holding company for:

Barclays bank
Standard and Chartered bank
Unilever
Tate and Lyle
Securicor
British Telecom
The Prince of Wales Business Leaders Forum, and
Aga Khan Foundation

I think you get the picture; it's big to say the least.

It manages the customs services of Mozambique, and through a company called Europe SA, it is in charge of all of the economic construction procurement for Bosnia. It is also in a joint venture with the Monaco-based company ES-KO, to provide all the food for United Nations peace keeping forces in Angola and Bosnia. So, the more war the more profit for the Crown Agents, and if it were to fail financially, then the British Taxpayer will have to foot the bill !!!!

The queen of England owns the 40,000 acre Duchy of Lancaster, and the 44,000 acre Duchy of Cornwall which gives Charles his income. In truth, it is the Crown that owns these assets, which are assigned to the ruling monarch, so long as they do as they are told. The Crown, it transpires, owns land in the UK to the tune of 40 million acres. The Queen owns over 300 residences around the country, and invests heavily in corporations like Rio Tinto Zinc, Royal Dutch Shell, ICI, and General Electric. This is no surprise as these companies are 100% Illuminati operations.

Rio Tinto is the largest mining company in the world and was established in 1873 by Hugh Matheson of the Global drug running operation Jardine Matheson. Rio Tinto was in at the start of the North Sea Oil, along with Texaco. They used the refineries of BP in which the Queen also has massive investments, so now you know where all the revenues from the North Sea oil reserves went - to the Crown Temple. This shows insider dealing on an individual basis enabling the Queen to make massive profits.

Another blatant conflict of interest to have been identified, was Rio Tinto's involvement in a cartel formed in 1971 to fix the price of uranium. A Federal grand jury and the 1976 US Senate Foreign Relations Committee, chaired by Frank Church, exposed the sting. It also included a company called Mary Kathleen Uranium of Australia. This company had been secretly encouraging the Aborigines to occupy uranium-rich lands in Australia to take these lands out of production in order to raise the price of uranium on the world market. The manipulated shortage of uranium had a serious effect on the American Westinghouse company who sought to take legal action against Rio Tinto for price rigging.

This strategy has been used in the USA against the Native Americans and throughout Africa. An American court ordered that Rio Tinto officials answer questions, but this was quashed by the British Law Lords. The Australian government passed legislation to the same effect. This was after the Australian Prime Minister, Gough Whitlam, had been dismissed from office by the Queen's Governor General of Australia, Sir John Kerr. Whitlam was pursuing a policy of buying out the mining and raw material cartels, like Rio Tinto and Anglo American, to stop them raping Australia's resource base, while giving nothing in return.

The Queen having enormous investments in both companies, removed Whitlam by using some of her wide range of prerogative powers, which by the way, she has in all commonwealth countries including Britain, which she can instigate when the Crown deem necessary, but of course in the minds of the masses the Queen has no powers today! Well I suppose she doesn't in that she is a puppet of the Crown Temple and ultimately, of the Roman system. Sir John Kerr, a former high level operative of British Intelligence, was made a member of the Privy Council and the Royal Victorian Order for his loyal and most profitable service to the Queen's portfolio.

He was later murdered however, when the truth about the removal of Gough Whitlam was in danger of coming out - how they look after their own! He was obviously outer circle, and a good man and would have exposed the lies of the inner circle. The Crown Cartels continue through a House of Windsor extremely secretive society called the Club of the Isles. It was named after King Edward VII, Queen Victoria's son.

The title is held today by Prince Charles. King Edward VII was heavily involved with the Black Nobility barons of 'the square mile of London' Financial District and helped them to engineer the Crimean War, the Russia - Japan War, the preparations for the First World War, and the Opium Wars against China. Through the central organisation of the Club of the Isles comes the fantastic web of interlocking directorships which holds apparently 'independent' companies in a network of common control and common agenda. Part of that web includes:

The Bank of England
Anglo American Corporation of South Africa
Rio Tinto
Minorco Minerals and Resources Corp
De Beers Consolidated Mines
De Beers Centenary AG
N.M Rothschild's Bank
Barclays Bank
Lloyds Bank
Lloyds Insurance Market
HSBC Bank
National Westminster Bank
Barings Bank
Schroders bank
Standard Chartered Bank
Hambros Bank
S.G Warburg
Toronto Dominion Bank
Johnson Matthey
Kleinwort Benson Group
Lazard Brothers
Lonrho
J.P Morgan and CO
Morgan Grenfell Group
British Petroleum
Shell and Royal Dutch Petroleum
Cadbury - Schweppes
Bat Industries
Assicurazioni Generali SpA (Venice Italy)
Courtaulds
General Electric
Cazeeenove and Co
Grand Metropolitan
Hanson PLC
HSBS (Hong Kong and Shanghai Bank)
Imperial and Chemical Industries (ICI)
Inchcape PLC
Inco Ltd.
ING Group
Jardine Matheson
Peninsular and Oriental Steam Navigation & Co (P & O ferries)
Pilkington Glass
Reuters Holdings
Glaxo Wellcome
Smithkline Beecham
Unilever and UnileverNV

Vickers PLC.

This is just a few of them. In 1999, Lonrho had 640 subsidiary companies itself; today, it has many more, and all of these companies have themselves, staggering numbers of subsidiaries. In studying the subsidiaries of the multi-nationals, you arrive at the fact that everything is controlled by the Crown, and that all of them lead back to operatives of the Roman Illuminati Church via the Knights Templar Church.

A fact worth noting is that just because a company like Pilkington Glass is now perceived to be owned by a non-British company, it has only moved from the British economy, not from the control or economy of the Illuminati who own everything, this type of movement is only a movement within the global conglomerate that is the New World Order and still earning for, and controlled by, the bloodline elite, albeit via a different branch of the elite tree.

Just look at some of the TV companies owned and thus controlled by General Electric:

NBC network
CNBC
MSNBC
Bravo
MUN2 TV
Sci-Fi channel
Trio
WNBC - New York
KNBC - Los Angeles
WMAQ - Chicago
WCAU - Philadelphia
KNTV - San Jose - San Francisco
KXAS - Dallas - Fort Worth
WRAC Washington
WTVJ - Miami
KNSDF - San Diego
WVIT - Hartford
WNCN - Raleigh
WCMH - Columbus
WVTM - Birmingham (USA)
WJAR - Providence
KVEA / KWHY - Los Angeles
WNJU - New York
WSCV - Miami
KTMD - Houston
WSNS - Chicago
KXTX - Dallas
KVDA - San Antonio
KSTS - San Francisco
KDRX - Phoenix
KNSO - Fresno
KMAS - Denver
WNEU - Boston / Merrimack
KHRR - Tucson
WKAQ - Puerto Rico
Universal Studios
NBC Universal Television Studio
NBC Universal Television Distribution.

This is one company controlling a major chunk of the TV dream state given out to the whole of America. Is it any wonder that Americans are completely under the control of the American elite?

Another important part of the Windsor network which is part of the Crown Temple, are the City Livery Companies. These purport to represent the various groups of merchants like the gun makers, stationers, newspaper makers, goldsmiths and the like. They are in fact, very secret societies, fundamental to the control of the City institutions and much further afield. In the 1350's, in the wake of the plague known to history as the Black Death, the government of the City passed from the ward councils to the City Livery Companies. In 1979, the year when Margaret Thatcher took power, the Honourable Company of Freeman of the City of London and of North America, began to hold meetings in New York and Toronto, and on 21st October 1991, the Association of Liverymen of the City of London in Hong Kong was founded and all their members were Architects (Freemasons). The late author Peter Jones, researched some of the Livery Companies in the 1990's for his book, 'The Obedience of Australia',

which exposed the manipulation which led to the removal by the Queen, of Australian Prime Minister, Gough Whitlam. These are some of the names which he found within these companies:

Engineers: The Duke of Edinburgh.

Airline Pilots and Navigators: The Duke of Edinburgh Prince Andrew

Butchers: Queen Mother, Lord Vesty (of the meat family and Lord Prior of the Order of St John of Jerusalem)

Merchant Tailors: Queen Mother, Lord Whitelaw

Glovers: Margaret Thatcher, Sir John Fieldhouse (Admiral of the Fleet during the Falklands conflict)

Poulterers: Margaret Thatcher, Duchess of Devonshire.

Fishmongers: Duke and Duchess of Devonshire, C.E.A

Hambro (Hambros Bank, Taylor Woodrow, and P&O), Lord Inchcape (Her Majesty's Lieutenant of London)

Goldsmiths: J.H Hambro.

Grocers: Edward Heath.

Salter's: Duke of Kent (Grand Master of English Freemasonry) Lord Armstrong.

Cloth workers: Sir Peter Gadson (a Grand Master of the United Grand Lodge), Lord Carrington (Thatcher's handler).

Another name prominent within these companies is McAlpine of the construction family.

You will of course have noted that Prince Philip heads the Pilots and Navigators, which gives indication as to whom is in control of the current attack on our right to travel by plane and the whole swath of legislation about to come out relative to air traffic, using the environment scam to force it through. Just as a matter of interest, the cheap-flight operator 'Easy Jet' is financed by the Warburg Bank which is part of the Rothschild empire which has been proved beyond doubt, to have funded the rise of Hitler's war machine on behalf of the Rothschilds.

The fact that they are now blaming these cheap flight operators for the rise in carbon emissions shows you why the Warburg bank has funded this airline, it is the catalyst for the introduction of the carbon emissions scam. Basically they will determine how much you, as a household, can travel. You have to look at this whole carbon emissions agenda as an attempt to instil a massive suppressing layer of control upon families and business via the introduction of quotas per household.

This will stifle people's movements to unimaginable levels. Don't forget that the House of Rothschild operates directly under the current British chief, Prince Philip. Prince Philip's whole family were supporters of the Nazi's as was he himself. In 1935, Prince Christoph, the husband of Philip's sister Sophie, was a colonel in the SS of Himmler's personal staff and head of the Forschungsamt, an elite intelligence operation controlled by Hermann Goering.

It was they who carried out the famous 'Night of the Long Knives' when Hitler removed his key opponents. Christoph and Sophie named their eldest child, Karl Adolf, after Hitler and Prince Philip was involved in his education. Christoph's brother, Philip of Hess, was related to the King of Italy and was the official liaison between the fascists of Italy and Germany. Also at the same time the British King Edward VIII, who was forced to abdicate in order the Queen Mother could be placed in the position of Chief Toad which meant she had to marry the lesser of the brothers, Bertie, the one she could obviously control.

King Edward VIII was well known to be a Nazi supporter. Prince Philip kept up very serious connections with Edward even after his abdication in 1936. Another of Edward's supporters, and mentor to Prince Philip, was the known paedophile and Satanist Lord Louis Mountbatten (Battenberg). Mountbatten was Philip's route into the House of Windsor. Mountbatten was the grandson of Queen Victoria and Prince Albert and was born at Windsor Castle in 1900. While Mountbatten was supposedly fighting on the British side during the war, he maintained serious communications with the Windsor's German Clan via his sister Louise, the Crown Princess of Sweden and wife of King Gustav. Louise was Prince Philip's aunt.

At the end of the war, in June 1945, the British King, George VI, the father of Queen Elizabeth and puppet of the Queen Mother, sent the former MI5 officer, Anthony Blunt, to the Kronberg Castle of Prince Philip's sister Sophie,

and her Nazi husband Prince Christoph of Hess, to recover correspondence between the British Royal Family and their Nazi relatives, for propaganda aimed at convincing the aristocrats of Britain they had not been in contact all along. Blunt was the 'surveyor of the Queens Pictures' and a world expert in the paintings of Poussin, the initiate who painted pictures called 'The Shepherds of Arcadia' which related to the Rennes-le-Chateau mysteries. Blunt was named as a member of a KGB unit inside British Intelligence along with Burgess, MacLean, and Philby, the fifth man was never named, but was in fact, Lord Victor Rothschild.

If you have seen the latest Bond movies, you hear the Character 'M' played by Dame Judy Dench state, 'in the cold war days intelligence operatives that made a big mistake had the common decency to defect', of course they would the intelligence services of the world are one and the same. When Blunt was finally caught in the 1980's, Queen Elizabeth II demanded he was not questioned on his clandestine mission to Kronberg Castle... So who controls the law?

Another important secret society within the Crown Temple is the Knights Grand Cross of the Order of the Bath, sounds pretty strange until you understand its symbolism. Both George Bush snr. and Ronald Reagan were given this title. The resurrection bath of alchemy, symbolises rebirth and purification or absolution. Baths are given to Masonic Knights of the Bath before they perform horrendous deeds, hence the term 'Blood Baths'.

The information in the last few paragraphs only hints at the true power of the Crown Temple. One has also to include all that the Vatican openly controls, to see the true extent of the power of the Roman Illuminati Church to which the Knights Templar Church is subordinate. Through all these networks and more, thirteen Royal Nefilim families control the world, and it is they who are carrying out all of the atrocities in the world at this present time, to carry out the agenda of the Elohim.

The Crown also owns massive parts of our coastline around this nation and 12 miles out to sea, in total about half of the coastline. Some of this is under the control of the Ministry of Defence which is itself controlled by the Crown. The current legislation, under which the National Trust will purchase some of this land from the MOD and coast not belonging to the MOD, changes nothing. The National Trust is 100% controlled by the Crown. We have the British Waterways agency, and the railways again controlling massive amounts of land, and we are effectively almost back to the middle ages now.

One of the greatest means to the Windsor land-grab is the:

CLUB OF THE ISLES

Controlling the World Wildlife Fund, WWF, this is one hell of a heinous operation and given the fact that Prince Philip inherited the position as the Queen's husband, becoming Commander of the Club of the Isles...then he is at the helm of genocide the likes of which the Holocaust could never imagine.

I see that the Royals are playing the good guys relative to the Sunni Muslims with the release of the Manchester man after 18 years in prison in Pakistan, this in itself shows you who operates President Musharaff of Pakistan, via such orders as the Order of the Mystic Shrine. This is important, given that Pakistan is now under attack from NATO forces, again controlled by the Inner City banking cartel which includes the Dutch and the Swiss.

So how does the Crown control all the MPs? Answer; via the whip system. All of the MPs which you vote in to represent you, are told how to vote each day by each party's leadership via the whips. So when any politician that has ever been and will be while this system exists, tells lies to the whole population the minute he or she opens his mouth and speaks. No matter what he speaks about, it is saying what he has been told to say, how to speak and when to speak. If it does not obey the whips, then his career is over. Thus the Crown need only control the people at leadership level or the cabinet of each political party and the Whips office, then through that clique of puppets, they demand obedience from all MPs down to the MPs sitting in each constituency, claiming to be acting on behalf of their constituents. The majority of MPs don't even get to see each bill before it goes to the vote, and indeed they don't need to as they are told how to vote on every Bill.

On Sunday 11th February 2007 on the political show 'Sunday AM', Giles Brandreth, a Conservative Party whip stated:

"As a whip, we understand each MP's marital problems, their drinking problems their financial problems, we know a lot about them. We then advise and guide them to making the right decisions".

Do you still feel that MPs act according to their own understanding and emotions? Of course they do not. This is the best I have witnessed from a politician handing you on a plate how the game of politics actually operates. They are all, through fear of their personal information being leaked; totally afraid of the whips, and so do the whips' bidding, which, of course, is the Crown's bidding. All MPs who speak at the box in the Commons do so under oath to the Bible positioned under the box. What does that tell you about those who operate as very

religious people (Blair) when they spew the bullshit? Blair is a high member of the Illuminati and that is why he can lie with ease as he speaks to the House and the people.

The Economic Techniques

The following is an excerpt from a document, dated May 1979, and which appears to be a statement of the methods and techniques used in the economic warfare which is being waged against all ordinary people at this time. Let me emphasise that these are not my words but that I am quoting the contents of an old and unverified document of unknown origin. Anonymous documents are a standard method of spreading disinformation, however, the statements quoted below are included because they have every appearance of being a factual New World Order strategy already being implemented.

Top Secret

Silent Weapons for Quiet Wars, An introductory programming manual, Operations Research Technical Manual TM-SW7905.1 This publication marks the 25th anniversary of the Third World War, called the "Quiet War", being conducted using subjective biological warfare, fought with "silent weapons." May 1979

Security

It is patently impossible to discuss social engineering or the automation of a society, i.e., the engineering of social automation systems (silent weapons) on a national or worldwide scale without implying extensive objectives of social control and destruction of human life, i.e., slavery and genocide. Whenever any person or group of persons in a position of great power and without full knowledge and consent of the public, uses such knowledge and methodologies for economic conquest - it must be understood that a state of domestic warfare exists between that person, or group of persons, and the public. The solution of today's problems requires an approach which is ruthlessly candid, with no agonizing over religious, moral or cultural values.

Historical Introduction

Silent weapon technology has evolved from Operations Research ("OR"), a strategic and tactical methodology developed under the Military Management in England during the Second World War. The original purpose of Operations Research was to study the strategic and tactical problems of air and land defence with the objective of effective use of limited military resources against foreign enemies (i.e., logistics). It was soon recognised by those in positions of power that the same methods might be useful for totally controlling a society, but better tools were needed.

Social engineering (the analysis and automation of a society) requires the correlation of great amounts of constantly changing economic information (data), so a high-speed computerised data-processing system was necessary which could predict when society would arrive at the point of capitulation. Mechanical computers were too slow, but the electronic computer fills the bill. The next breakthrough was the development of the simplex method of linear programming in 1947 by the mathematician George B. Dantzig. Then in 1948, the transistor, promised great expansion of the computer field by reducing space and power requirements.

With these three inventions, those in positions of power strongly suspected that it was possible for them to control the whole world. Immediately, the Rockefeller Foundation got in on the ground floor by making a four-year grant to Harvard College, funding the Harvard Economic Research Project for the study of the structure of the American Economy. One year later, in 1949, The United States Air Force joined in. In 1952 the grant period terminated, and a high-level meeting of the Elite was held to determine the next phase of social Operations Research. The Harvard project had been very fruitful, as is borne out by the publication of some of its results in 1953 suggesting the feasibility of economic (social) engineering. (Studies in the Structure of the American Economy - copyright 1953 by Wassily Leontief, International Science Press Inc., White Plains, New York).

Engineered during the last half of the 1940's, by 1954 the new Quiet-War machine was ready. With the creation of the maser in 1954, the promise of unlocking unlimited sources of fusion atomic energy from the heavy hydrogen in sea water and the consequent availability of unlimited social power was a possibility only decades away. The combination was irresistible. The Quiet War was quietly declared by the International Elite at a meeting held in 1954. Although the silent weapons system was nearly exposed 13 years later, the evolution of the new weapon-system has never suffered any major setbacks. This year of 1979 marks the 25th anniversary of the beginning of the Quiet War. Already this domestic war has had many victories on many fronts throughout the world.

Political Introduction

In 1954 it was well recognised by those in positions of authority, that it would be only a few decades, before the general public would be able to grasp and upset the cradle of power, for the elements of the new silent-weapon

technology were as accessible for use in providing a public utopia as they were for providing a private utopia. So, the issue of primary concern, namely that of dominance, revolved around the subject of the energy sciences.

Energy

Energy is recognised as the key to all activity on earth. Natural science is the study of the sources and control of natural energy, and social science (theoretically expressed as economics) is the study of the sources and control of social energy. Both are bookkeeping systems based on mathematics. Therefore, mathematics is the primary energy science and the bookkeeper can be king if the public can be kept ignorant of the methodology of the bookkeeping.

All science is merely a means to an end. The means is knowledge. The end is control. Beyond this remains only one issue: Who will be the beneficiary? In 1954 this was the issue of primary concern. Although the so-called "moral issues" were raised, in view of the law of natural selection it was agreed that a nation or world of people who will not use their intelligence are no better than animals who do not have intelligence. Such people are beasts of burden and steaks on the table by choice and consent.

Consequently, in the interest of future world order, peace, and tranquillity, it was decided to wage a private quiet war against the American public with an ultimate objective of permanently shifting the natural and social energy (wealth) of the undisciplined and irresponsible many into the hands of the self-disciplined, responsible, and "worthy" few.

In order to implement this objective, it was necessary to create, secure, and apply new weapons which, as it turned out, were a class of weapons so subtle and sophisticated in their principle of operation and public appearance as to earn for themselves the name of "silent weapons." In conclusion, the objective of economic research, as conducted by the magnates of capital (banking) and the industries of commodities (goods and services), is the establishment of an economy which is totally predictable and which can be manipulated.

In order to achieve this totally predictable economy, the low-class elements of society must be brought under total control, i.e., They must be housebroken, trained, and assigned a yoke and long-term social duties from a very early age, before they have an opportunity to question the propriety of the matter. In order to achieve such conformity, the lower-class family unit must be disintegrated by a process of increasing preoccupation of the parents and the establishment of government-operated day-care centres for the occupationally orphaned children.

The quality of education given to the lower class must be of the poorest sort, so that the moat of ignorance isolating the inferior class from the superior class is and always remains, incomprehensible to the inferior class. With such an initial handicap, even bright lower class individuals have little if any hope of extricating themselves from their assigned lot in life. This form of slavery is essential to maintain some measure of social order, peace, and tranquillity for the ruling upper class.

Descriptive Introduction to the Silent Weapon

Everything which can be expected from an ordinary weapon is also expected from a silent weapon by its creators, but only in its own manner of functioning. It shoots situations, instead of bullets; its propellant is data processing, instead of the conventional chemical explosion. The power originates from bits of data in a computer, instead of grains of gunpowder inside a gun. The operator is a computer programmer, instead of a military marksman, and the orders are issued by a banking magnate, instead of a military general. It makes no obvious explosive noises, causes no obvious physical or mental injuries, and does not interfere in an obvious way with anyone's daily social life.

However, it makes an unmistakable "noise," causes unmistakable physical and mental damage, and interferes unmistakably with daily social life, that is, in ways which are unmistakable to a trained observer who knows what to look for. The public cannot comprehend this weapon, and therefore cannot believe that they are being attacked and subdued by a weapon. The public might instinctively feel that something is wrong, but because of the technical nature of the silent weapon, they cannot express their feeling in any rational way, or handle the problem with intelligence. Therefore, they do not know how to call for help, nor do they know how to associate with others to defend themselves against it.

When a silent weapon is applied gradually, the public adjusts and adapts to its presence and learns to tolerate its encroachment on their lives until the psychological pressure (applied via economic methods) becomes too great and they crack up. Therefore, in a way, the silent weapon can be considered to be a type of biological weapon. It attacks the vitality, options, and mobility of the individuals of a society by knowing, understanding, manipulating, and attacking their sources of natural and social energy, and their physical, mental, and emotional strengths and weaknesses.

Theoretical Introduction

"Give me control over a nation's currency, and I care not who makes its laws." - Mayer Amschel Rothschild (1743

- 1812). Today's silent weapons technology is an outgrowth of a simple idea discovered, succinctly expressed, and effectively applied by Mr. Mayer Amschel Rothschild. Mr. Rothschild discovered the missing passive component of economic theory known as economic inductance. He, of course, did not think of his discovery in these twentieth century terms, and, to be sure, mathematical analysis had to wait for the Second Industrial Revolution, the rise of the theory of mechanics and electronics, and finally, the invention of the electronic computer before it could be effectively applied in the control of the world economy.

General Energy Concepts

In the study of energy systems, there always appears three elementary concepts. These are:

Potential Energy,
Kinetic Energy, and
Energy Dissipation.

Corresponding to these concepts, there are three idealised, essentially pure physical counterparts called passive components.

In the science of physical mechanics, the phenomenon of Potential Energy is associated with a physical property called Elasticity or stiffness, and can be represented by a stretched spring. In electronic science, Potential energy is stored in a capacitor instead of a spring. This property is called Capacitance instead of Elasticity.

In the science of physical mechanics, the phenomenon of Kinetic Energy is associated with a physical property called Inertia or Mass, and can be represented by a mass or a flywheel in motion. In electronic science, Kinetic Energy is stored in an inductor (in a magnetic field) instead of a mass. This property is called Inductance instead of Inertia.

In the science of physical mechanics, the phenomenon of Energy Dissipation is associated with a physical property called Friction or Resistance, and can be represented by a dashpot or other device which converts energy into heat. In electronic science, Energy Dissipation is performed by an element called either a Resistor.

In economics the equivalents of these three energy concepts are:

Economic Capacitance - **Capital** (money, stock/inventory, investments in buildings and durables, etc.)

Economic Conductance - **Goods** (production flow coefficients)

Economic Inductance - **Services** (the influence of the industrial population on output)

All of the mathematical theory developed in the study of one energy system (e.g., mechanics, electronics, etc.) can be immediately applied in the study of any other energy system (e.g., economics).

Mr Rothschild's Energy Discovery

What Mr. Rothschild discovered was the basic principle of power, influence, and control over people as applied to economics. That principle is "when you assume the appearance of power, people soon give it to you." Mr. Rothschild had discovered that currency or deposit loan accounts had the required appearance of power that could be used to induce people (inductance, with people corresponding to a magnetic field) into surrendering their real wealth in exchange for a promise of greater wealth (instead of real compensation). They would put up real collateral in exchange for a loan of promissory notes. Mr. Rothschild found that he could issue more notes than he had backing for, provided he had someone's stock of gold to show his customers as a persuader.

Mr. Rothschild loaned his promissory notes to individual and to governments. These would create overconfidence. Then he would make money scarce, tighten control of the system, and collect the collateral through the obligation of contracts. The cycle was then repeated. These pressures could be used to ignite a war. Then he would control the availability of currency to determine who would win the war. Any government which agreed to give him control of its economic system got his support. Collection of debts was guaranteed by economic aid to the enemy of the debtor. The profit derived from this economic methodology made Mr. Rothschild all the more able to expand his wealth. He found that the public greed would allow currency to be printed by government order beyond the limits (inflation) of backing in precious metal or the production of goods and services.

Apparent Capital as "Paper" Inductor

In this structure, credit, presented as a pure element called "currency," has the appearance of capital, but is in effect, negative capital. Hence, it has the appearance of service, but it is, in fact, indebtedness or debt. It is therefore an economic inductance instead of an economic capacitance, and if balanced in no other way, will be balanced by the negation of population (war, genocide). The total sum of goods and services represents real capital and it is called the **Gross National Product**, and currency may be printed up to this level and still represent economic capacitance; but currency printed beyond this level is subtractive, represents the introduction of economic inductance, and so becomes notes of indebtedness.

War is therefore the balancing of the system by killing the true creditors (the public which has been taught to exchange true value for inflated currency) and falling back on whatever is left of the resources of nature and regeneration of those resources. Mr. Rothschild had discovered that currency gave him the power to rearrange the economic structure to his own advantage, to shift economic inductance to those economic positions which would encourage the greatest economic instability and oscillation.

The final key to economic control had to wait until there was sufficient data and high-speed computing equipment to keep close watch on the economic oscillations created by price shocking and excess paper energy credits - paper inductance/inflation.

Breakthrough

The aviation field provided the greatest evolution in economic engineering by way of the mathematical theory of shock testing. In this process, a projectile is fired from an airframe on the ground and the impulse of the recoil is monitored by vibration transducers connected to the airframe and wired to chart recorders. By studying the echoes or reflections of the recoil impulse in the airframe, it is possible to discover critical vibrations in the structure of the airframe which either vibrations of the engine or aeolian vibrations of the wings, or a combination of the two, might reinforce resulting in a resonant self-destruction of the airframe in flight. From the standpoint of engineering, this means that the strengths and weaknesses of the structure of the airframe in terms of vibrational energy can be discovered and manipulated.

Application in Economics

To use this method of airframe shock testing in economic engineering, the prices of commodities are shocked, and the public consumer reaction is monitored. The resulting echoes of the economic shock are interpreted theoretically by computers and the psycho-economic structure of the economy is thus discovered. It is by this process that partial differential and difference matrices are discovered that define the family household and make possible its evaluation as an economic industry (dissipative consumer structure). Then the response of the household to future shocks can be predicted and manipulated, and society becomes a well-regulated animal with its reins under the control of a sophisticated computer-regulated social energy bookkeeping system. Eventually every individual element of the structure comes under computer control through a knowledge of personal preferences, such knowledge guaranteed by computer association of consumer preferences (universal product code - the striped bar codes on packages) with identified consumers (initially identified through the use of a credit card and later through a permanent "tattooed" body number invisible under normal ambient illumination).

The Economic Model

The Harvard Economic Research Project (1948-1952) was an extension of World War II Operations Research. Its purpose was to discover the science of controlling an economy: at first the American economy, and then the world economy. It was felt that with sufficient mathematical foundation and data, it would be nearly as easy to predict and control the trend of an economy as to predict and control the trajectory of a projectile. Such has proven to be the case. Moreover, the economy has been transformed into an accurately targeted guided missile.

The immediate aim of the Harvard project was to discover the economic structure, what forces can change that structure, how the behaviour of the structure can be predicted, and how it can be manipulated. What was needed was a well-organised knowledge of the mathematical structures and interrelationships of investment, production, distribution, and consumption. Briefly, it was discovered that an economy obeyed the same laws as electricity and that all of the mathematical theory and practical and computer know-how developed for the electronic field could be directly applied in the study of economics. This discovery was not openly declared, and its more subtle implications were, and are, kept as a closely guarded secret, for example, in an economic model, human life is measured in dollars, and that the electric spark generated when opening a switch connected to an active inductor is mathematically the same as starting a war.

The greatest hurdle which theoretical economists faced was the accurate description of the household as an industry. This is a challenge because consumer purchases are a matter of choice which in turn is influenced by family income, purchase price, and other economic factors. This hurdle was cleared in an indirect and statistically approximate way by an application of shock testing to determine the current characteristics, called current technical coefficients, of a household industry. Finally, because problems in theoretical electronics can be translated very easily into problems of theoretical economics, and the solution translated back again, it follows that only a book of language translation and concept definition needed to be written for economics. The remainder could be got from standard works on mathematics and electronics. This makes the publication of books on advanced economics unnecessary, and greatly simplifies the silent war project security.

Industrial Diagrams

An ideal industry is defined as a device which receives value from other industries in several forms and converts them into one specific product for sales and distribution to other industries. It has several inputs and one output. What the public normally thinks of as one industry is really an industrial complex, where several industries under one roof produce one or more products.

Three Industrial Classes

Industries fall into three categories or classes by type of output:

Class 1 - **Capital** (resources)

Class 2 - **Goods** (commodities or use - dissipative)

Class 3 - **Services** (action of population).

Class 1 industries exist at three levels:

(a) **Nature** - sources of energy and raw materials.

(b) **Government** - printing of currency equal to the gross national product (GNP), and extension of currency in excess of GNP.

(c) **Banking** - loaning of money for interest, and extension (inflation/counterfeiting) of economic value through deposit loan accounts.

Class 2 industries exist as producers of tangible or consumer (dissipated) products. This sort of activity is usually recognised and labelled by the public as "industry."

Class 3 industries are those which have service rather than a tangible product as their output. These industries are called

(a) **Households**, and

(b) **Governments**. Their output is human activity of a mechanical sort, and their basis is population.

Aggregation

The whole economic system can be represented by a three-industry model if one allows the names of the outputs to be:

(1) Capital,

(2) Goods, and

(3) Services.

The problem with this representation is that it would not show the influence of, say, the textile industry on the steel industry. This is because both the textile industry and the steel industry would be contained within a single classification called the "goods industry" and by this process of combining or aggregating these two industries under one system block they would lose their economic individuality.

The E- Model

A national economy consists of simultaneous flows of production, distribution, consumption, and investment. If all of these elements including labour and human functions are assigned a numerical value using common units of measure, say, US dollars at their 1939 value, then this flow can be further represented by a current flow in an electronic circuit, and its behaviour can be predicted and manipulated with useful precision.

The three ideal passive energy components of electronics, the capacitor, the resistor, and the inductor correspond to the three ideal passive energy components of economics called the pure industries of capital, goods, and services.

Economic Capacitance represents the storage of capital in one form or another.

Economic Conductance represents the level of conductance of materials for the production of goods.

Economic Inductance represents the inertia of economic value in motion. This is a population phenomenon known as services.

Economic Inductance

An electrical inductor (e.g., a coil or wire) has an electric current as its primary phenomenon and a magnetic field as its secondary phenomenon (inertia). Corresponding to this, an economic inductor has a flow of economic value as its primary phenomenon and a population field as its secondary field phenomenon of inertia. When the flow of economic value (e.g., money) diminishes, the human population field collapses in order to keep the economic value (money) flowing (extreme case - war). This public inertia is a result of consumer buying habits, expected standard of living, etc., and is generally a phenomenon of self-preservation.

Inductive Factors to Consider

(1) Population

(2) Magnitude of the economic activities of the government

(3) The method of financing these government activities

(See Peter-Paul Principle - inflation of the currency.)

Translation

(a few examples will be given.)

Charge - coulombs - dollars (1939).

Current Flow - amperes (coulombs per second) - dollars of flow per year.

Motivating Force - volts - dollars (output) demand.

Conductance - amperes per volt - dollars of flow per year per dollar demand.

Capacitance - coulombs per volt - dollars of production inventory/stock per dollar demand.

Time-Flow Relationships and Self-Destructive Oscillations

An ideal industry may be symbolised electronically in various ways. The simplest way is to represent a demand by a voltage and a supply by a current. When this is done, the relationship between the two becomes what is called an admittance, which can result from three economic factors:

- (1) **Hindsight flow**,
- (2) **Present flow**, and
- (3) **Foresight flow**.

Foresight flow is the result of that property of living entities to cause energy (food) to be stored for a period of low energy (e.g., a winter season). It consists of demands made upon an economic system for that period of low energy (winter season). In a production industry it takes several forms, one of which is known as production stock or inventory. In electronic symbology this specific industry demand (a pure capital industry) is represented by capacitance and the stock or resource is represented by a stored charge. Satisfaction of an industry demand suffers a lag because of the loading effect of inventory priorities.

Present flow ideally involves no delays. It is, so to speak, input today for output today, a "hand to mouth" flow. In electronic symbology, this specific industry demand is represented by a conductance which is then a simple economic valve (a dissipative element).

Hindsight flow is known as habit or inertia. In electronics this phenomenon is the characteristic of an inductor (economic analogue = a pure service industry) in which a current flow (economic analogue = flow of money) creates a magnetic field (economic analogue = active human population) which, if the current (money flow) begins to diminish, will collapse (war) to maintain the current (flow of money - energy).

Other large alternatives to war as economic inductors or economic flywheels are an open-ended social welfare program, or an enormous (but fruitful) open-ended space program. The problem with stabilising the economic system is that there is too much demand on account of:

- (1) Too much greed and
- (2) Too much population.

This creates excessive economic inductance which can only be balanced with economic capacitance (true resources or value - e.g., in goods or services).

The social welfare program is nothing more than an open-ended credit balance system which creates a false capital industry to give non-productive people a roof over their heads and food in their stomachs. This can be useful, however, because the recipients become state property in return for the "gift," and form a standing army for the Elite - as he who pays the piper picks the tune. Those who get hooked on the economic drug, must go to the Elite for a fix. In this, the method of introducing large amounts of stabilising capacitance is by borrowing on the future "credit" of the world. This is a fourth law of motion - **onset**, and consists of performing an action and leaving the system before the reflected reaction returns to the point of action - a delayed reaction.

The means of surviving the reaction is by changing the system before the reaction can return. By this means, politicians become more popular in their own time and the public pays later. In fact, the measure of such a politician is the delay time. The same thing is achieved by a government by printing money beyond the limit of the gross national product, and economic process called inflation. This puts a large quantity of money into the hands of the public and maintains a balance against their greed, creates a false self-confidence in them and, for a while, stays the wolf from the door.

They must eventually resort to war to balance the account, because war ultimately is merely the act of destroying the creditor, and the politicians are the publicly hired hit men that justify the act to keep the responsibility and blood off the public conscience. If the people really cared about their fellow man, they would control their appetites (greed, procreation, etc.) so that they would not have to operate on a credit or welfare social system which steals from the worker to satisfy the burn. Since most of the general public will not exercise restraint, there are only two alternatives to reduce the economic inductance of the system.

- (1) Let the populace bludgeon each other to death in war, which will only result in a total destruction of the living earth.

(2) Take control of the world by the use of economic "silent weapons" in a form of "quiet warfare" and reduce the economic inductance of the world to a safe level by a process of benevolent slavery and genocide.

The latter option has been taken as the obviously better option. At this point it should be crystal clear to the reader why absolute secrecy about the silent weapons is necessary. The general public refuses to improve its own mentality and its faith in its fellow man. It has become a herd of proliferating barbarians, and, so to speak, a blight upon the face of the earth. They do not care enough about economic science to learn why they have not been able to avoid war despite religious morality, and their religious or self-gratifying refusal to deal with earthly problems, places the solution of the earthly problem beyond their reach.

It is left to those few who are truly willing to think and survive, as the fittest to survive, to solve the problem for themselves as the few who really care. Otherwise, exposure of the silent weapon would destroy our only hope of preserving the seed of the future true humanity.

The Household Industry

The industries of finance (banking), manufacturing, and government, real counterparts of the pure industries of capital, goods, and services, are easily defined because they are generally logically structured. Because of this their processes can be described mathematically and their technical coefficients can be easily deduced. This, however, is not the case with the service industry known as the household industry.

Household Models

The problem which a theoretical economist faces is that the consumer preferences of any household are not easily predictable and the technical coefficients of any one household tend to be a non-linear, very complex, and variable function of income, prices, etc. Computer information derived from the use of the universal product code in conjunction with credit-card purchase as an individual household identifier, could change this state of affairs, but the Universal Product Code method is not yet available on a national or even a significant regional scale. To compensate for this data deficiency, an alternate indirect approach of analysis has been adopted known as economic shock testing. This method, widely used in the aircraft manufacturing industry, develops an aggregate statistical sort of data.

Applied to economics, this means that all of the households in one region or in the whole nation are studied as a group or class rather than individually, and the mass behaviour rather than the individual behaviour is used to discover useful estimates of the technical coefficients governing the economic structure of the hypothetical single-household industry. One method of evaluating the technical coefficients of the household industry depends upon shocking the prices of a commodity and noting the changes in the sales of all of the commodities.

Economic Shock Testing

In recent times, the application of Operations Research to the study of the public economy has been obvious for anyone who understands the principles of shock testing. In the shock testing of an aircraft airframe, the recoil impulse of firing a gun mounted on that airframe causes shock waves in that structure which tell aviation engineers the conditions under which some parts of the airplane or the whole airplane or its wings will start to vibrate or flutter like a guitar string, a flute reed, or a tuning fork, and disintegrate or fall apart in flight. Economic engineers achieve the same result in studying the behaviour of the economy and the consumer public by carefully selecting a staple commodity such as beef, coffee, gasoline, or sugar, and then causing a sudden change or shock in its price or availability, thus kicking everybody's budget and buying habits out of shape. They then observe the shock waves which result by monitoring the changes in advertising, prices, and sales of that and other commodities.

The objective of such studies is to acquire the know-how to set the public economy into a predictable state of motion or change, even a controlled self-destructive state of motion which will convince the public that certain "expert" people should take control of the money system and re-establish security (rather than liberty and justice) for all. When the subject citizens are rendered unable to control their financial affairs, they, of course, become totally enslaved, and a source of cheap labour. Not only the prices of commodities, but also the availability of labour can be used as the means of shock testing. Labour strikes deliver excellent tests shocks to an economy, especially in the critical service areas of trucking (transportation), communication, public utilities (energy, water, garbage collection), etc. By shock testing, it is found that there is a direct relationship between the availability of money flowing in an economy and the real psychological outlook and response of masses of people dependent upon that availability. For example, there is a measurable quantitative relationship between the price of gasoline and the probability that a person would experience a headache, feel a need to watch a violent movie, smoke a cigarette, or go to a tavern for a mug of beer.

It is most interesting that, by observing and measuring the economic models by which the public tries to run from their problems and escape from reality, and by applying the mathematical theory of Operations Research, it is possible to program computers to predict the most probable combination of created events (shocks) which will

bring about a complete control and subjugation of the public through a subversion of the public economy (by shaking the plum tree).

Introduction to Economic Amplifiers

Economic Amplifiers are the active components of economic engineering. The basic characteristic of any amplifier (mechanical, electrical, or economic) is that it receives an input control signal and delivers energy from an independent energy source to a specified output terminal in a predictable relationship to that input control signal. The simplest form of an economic amplifier is a device called advertising. If a person is spoken to by a T.V. advertiser as if he were a twelve-year-old, then, due to suggestibility, he will, with a certain probability, respond or react to that suggestion with the uncritical response of a twelve-year-old and will reach into his economic reservoir and deliver its energy to buy that product on impulse when he passes it in the store.

An Economic Amplifier may have several inputs and output. Its response might be instantaneous or delayed. Its circuit symbol might be a rotary switch if its options are exclusive, qualitative, "go" or "no-go", or it might have its parametric input/output relationships specified by a matrix with internal energy sources represented. Whatever its form might be, its purpose is to govern the flow of energy from a source to an output sink in direct relationship to an input control signal. For this reason, it is called an active circuit element or component. Economic Amplifiers fall into classes called strategies, and, in comparison with electronic amplifiers, the specific internal functions of an economic amplifier are called logistical instead of electrical. Therefore, economic amplifiers not only deliver power gain but also, in effect, are used to cause changes in the economic circuitry.

In the design of an economic amplifier we must have some idea of at least five functions ,which are:

- (1) The available input signals,
- (2) The desired output-control objectives,
- (3) The strategic objective,
- (4) The available economic power sources,
- (5) The logistical options.

The process of defining and evaluating these factors and incorporating the economic amplifier into an economic system has been popularly called "game theory". The design of an economic amplifier begins with a specification of the power level of the output, which can range from personal to national. The second condition is accuracy of response, i.e., how accurately the output action is a function of the input commands. High gain combined with strong feedback helps to deliver the required precision. Most of the error will be in the input data signal. Personal input data tends to be specified, while national input data tends to be statistical.

Short List of Inputs

General sources of information:

- (1) Telephone taps
- (2) Surveillance
- (3) Analysis of garbage
- (4) Behaviour of children in school

Standard of living by:

- (1) Food
- (2) Clothing
- (3) Shelter
- (4) Transportation

Social contacts:

- (1) Telephone - itemized record of calls
- (2) Family - marriage certificates, birth certificates, etc.
- (3) Friends, associates, etc.
- (4) Memberships in organizations
- (5) Political affiliation

The Personal Paper Trail

Personal buying habits, i.e., personal consumer preferences:

- (1) Bank accounts
- (2) Credit-card purchases

(3) "Tagged" credit-card purchases - those with a Universal Product Code

Assets:

- (1) Bank accounts
- (2) Savings accounts
- (3) Property
- (4) Business
- (5) Vehicles, etc.
- (6) Safety deposit at a bank
- (7) Stock market purchases

Liabilities:

- (1) Creditors
- (2) Enemies (see - legal)
- (3) Loans
- (4) Consumer credit

Government sources (ploys)*:

- (1) Welfare
- (2) Social Security
- (3) U.S.D.A. surplus food
- (4) Dole
- (5) Grants
- (6) Subsidies

*Principle of this ploy - the citizen will almost always make the collection of information easy if he can operate on the "free sandwich principle" of "eat now, and pay later."

Government sources (via intimidation) :

- (1) Internal Revenue Service
- (2) OSHA
- (3) Census
- (4) etc.

Other government sources - surveillance of U.S. mail.

Habit Patterns - Programming

Strengths and weaknesses:

- (1) Activities (sports, hobbies, etc.)
- (2) See "legal" (fear, anger, etc. - crime record)
- (3) Hospital records (drug sensitivities, reaction to pain, etc.)
- (4) Psychiatric records (fears, angers, disgusts, adaptability, reactions to stimuli, violence, suggestibility or hypnosis, pain, pleasure, love, and sex)

Methods of coping - of adaptability - behaviour:

- (1) Consumption of alcohol
- (2) Consumption of drugs
- (3) Entertainment
- (4) Religious factors influencing behaviour
- (5) Other methods of escaping from reality

Payment modus operandi (MO) - pay on time, etc.:

- (1) Payment of telephone bills
- (2) Energy purchases (electrical, gas,...)
- (3) Water purchases
- (4) Repayment of loans
- (5) House payments
- (6) Vehicle payments

(7) Payments on credit cards

Political sensitivity:

- (1) Beliefs
- (2) Contacts
- (3) Position
- (4) Strengths/weaknesses
- (5) Projects/activities

Legal inputs - behavioural control (Excuses for investigation, search, arrest, or use of force to modify behaviour):

- (1) Court records
- (2) Police records - NCIC
- (3) Driving record
- (4) Reports made to police
- (5) Insurance information
- (6) Anti-establishment acquaintances

National Input Information

Business sources (via I.R.S., etc.):

- (1) Prices of commodities
- (2) Sales
- (3) Investments in
 - (a) stocks/inventory
 - (b) production tools and machinery
 - (c) buildings and improvements
 - (d) the stock market

Banks and credit bureaus:

- (1) Credit information
- (2) Payment information

Miscellaneous sources:

- (1) Polls and surveys
- (2) Publications
- (3) Telephone records
- (4) Energy and utility purchases

Short List of Inputs

Outputs - create controlled situations - manipulation of the economy, hence society - control of compensation and income.

Sequence:

- (1) Allocates opportunities.
- (2) Destroys opportunities.
- (3) Controls the economic environment.
- (4) Controls the availability of raw materials.
- (5) Controls capital.
- (6) Controls bank rates.
- (7) Controls the inflation of the currency.
- (8) Controls the possession of property.
- (9) Controls industrial capacity.
- (10) Controls manufacturing.
- (11) Controls the availability of goods (commodities) .
- (12) Controls the prices of commodities.
- (13) Controls services, the labour force, etc.
- (14) Controls payments to government officials
- (15) Controls the legal functions.
- (16) Controls the personal data files - uncorrectable by the party slandered.
- (17) Controls advertising.
- (18) Controls media contact.

- (19) Controls material available for T.V. viewing.
- (20) Disengages attention from real issues.
- (21) Engages emotions.
- (22) Creates disorder, chaos, and insanity.
- (23) Controls design of more probing tax forms.
- (24) Controls surveillance.
- (25) Controls the storage of information.
- (26) Develops psychological analyses and profiles of individuals.
- (27) Controls sociological factors.
- (28) Controls health options.
- (29) Preys on weakness.
- (30) cripples strengths.
- (31) leaches wealth and substance.

Table of Strategies

Do This	To Get This
Keep the public ignorant	Less public organisation
Maintain access control	Required reaction to output (prices, sales)
Create preoccupation	Lower defences
Attack the family unit	Control the education of the young
Give less cash and more credit and dole	More self-indulgence and more data
Attack the privacy of the church	Destroy faith in this sort of government
Social conformity	Computer programming simplicity
Minimise tax protests	Maximum economic data, minimum enforcement problems
Stabilise the consent	Simplicity coefficients
Tighten control of variables	Simpler computer input data - greater predictability
Establish boundary conditions	Problem simplicity / solutions of differential and difference equations
Proper timing	Less data shift and blurring
Maximise control	Minimum resistance to control
Collapse of currency	Destroy the faith of the American people in each other

Diversion, the Primary Strategy

Experience has shown that the simplest method of securing a silent weapon and gaining control of the public is to keep the public undisciplined and ignorant of the basic system principles on the one hand, while keeping them confused, disorganised, and distracted with matters of no real importance on the other hand. This is achieved by:

- (1) Disengaging their minds; sabotaging their mental activities; providing a low-quality program of public education in mathematics, logic, systems design and economics; and discouraging technical creativity.
- (2) Engaging their emotions, increasing their self-indulgence and their indulgence in emotional and physical activities, by:
 - (a) Unrelenting emotional affronts and attacks (mental and emotional rape) by way of constant barrage of sex, violence, and wars in the media - especially the T.V. and the newspapers.
 - (b) Giving them what they desire - in excess - "junk food for thought" - and depriving them of what they really need.
- (3) Rewriting history and law and subjecting the public to the deviant creation, thus being able to shift their thinking from personal needs to highly fabricated outside priorities.

These preclude their interest in, and discovery of, the silent weapons of social automation technology. The general rule is that there is a profit in confusion; the more confusion, the more profit. Therefore, the best approach is to create problems and then offer solutions.

Diversion Summary

Media: Keep the adult public attention away from the real social issues, and captivated by matters of no real importance.

Schools: Keep the young public ignorant of real mathematics, real economics, real law, and real history.

Entertainment: Keep the public entertainment below a sixth-grade (12 year old) level.

Work: Keep the public busy, busy, busy, with no time to think; back on the farm with the other animals.

Consent, the Primary Victory

A silent weapon system operates upon data obtained from a docile public by legal (but not always lawful) force. Much information is made available to silent weapon systems programmers through the Internal Revenue Service. (See Studies in the Structure of the American Economy for an I.R.S. source list). This information consists of the enforced delivery of well-organised data contained in federal and state tax forms, collected, assembled, and submitted by slave labour provided by taxpayers and employers. Furthermore, the number of such forms submitted to the I.R.S. is a useful indicator of public consent, an important factor in strategic decision making. Other data sources are given in the Short List of Inputs.

Consent Coefficients - numerical feedback indicating victory status. Psychological basis: When the government is able to collect tax and seize private property without just compensation, it is an indication that the public is ripe for surrender and is consenting to enslavement and legal encroachment. A good and easily quantified indicator of harvest time is the number of public citizens who pay income tax despite an obvious lack of reciprocal or honest service from the government.

Amplification Energy Sources

The next step in the process of designing an Economic Amplifier is discovering the energy sources. The energy sources which support any primitive economic system are, of course, a supply of raw materials, and the consent of the people to labour and consequently assume a certain rank, position, level, or class in the social structure, i.e., to provide labour at various levels in the pecking order. Each class, in guaranteeing its own level of income, controls the class immediately below it, hence preserves the class structure. This provides stability and security, but also government from the top. As time goes on and communication and education improve, the lower-class elements of the social labour structure become knowledgeable and envious of the good things that the upper-class members have. They also begin to attain a knowledge of energy systems and the ability to enforce their rise through the class structure. This threatens the sovereignty of the Elite.

If this rise of the lower classes can be postponed long enough, the Elite can achieve energy dominance, and labour by consent no longer will hold a position of an essential energy source. Until such energy dominance is absolutely established, the consent of people to labour and let others handle their affairs must be taken into consideration, since failure to do so could cause the people to interfere in the final transfer of energy sources to the control of the Elite. It is essential to recognise that at this time, public consent is still an essential key to the release of energy in the process of economic amplification. Therefore, consent as an energy release mechanism will now be considered.

Logistics

The successful application of a strategy requires a careful study of inputs, outputs, the strategy connecting the inputs and the outputs, and the available energy sources to fuel the strategy. This study is called "Logistics". A logistical problem is studied at the elementary level first, and then levels of greater complexity are studied as a synthesis of elementary factors. This means that a given system is analysed, i.e., broken down into its sub-systems, and these in turn are analysed, until by this process, one arrives at the logistical "atom," the individual.

The Artificial Womb

From the time a person leaves his mother's womb, his every effort is directed towards building, maintaining, and withdrawing into artificial wombs, various sorts of substitute protective devices or shells. The objective of these artificial wombs is to provide a stable environment for both stable and unstable activity; to provide a shelter for the evolutionary processes of growth and maturity - i.e., survival; to provide security for freedom and to provide defensive protection for offensive activity. This is equally true of both the general public and the Elite. However, there is a definite difference in the way each of these classes go about the solution of problems.

The Political Structure of a Nation - Dependency

The primary reason why the individual citizens of a country create a political structure is a subconscious wish or desire to perpetuate their own dependency relationship of childhood. Simply put, they want a human god to eliminate all risk from their life, pat them on the head, kiss their bruises, put a chicken on every dinner table, clothe their bodies, tuck them into bed at night, and tell them that everything will be all right when they wake up in the morning. This public demand is incredible, so the human god, the politician, meets incredibility with incredibility by promising the world and delivering nothing. So who is the bigger liar? The public? or The "godfather"? This public behaviour is surrender born of fear, laziness, and expediency. It is the basis of the welfare state as a strategic weapon, useful against a disgusting public.

Action / Offence

Most people want to be able to subdue and/or kill other human beings who disturb their daily lives, but they do not want to have to cope with the moral and religious issues which such an overt act on their part might raise. Therefore, they assign the dirty work to others (including their own children) so as to keep the blood off their hands. They rave about the humane treatment of animals and then sit down to a delicious hamburger from a whitewashed slaughterhouse down the street and out of sight. But even more hypocritical, they pay taxes to finance a professional association of hit men collectively called politicians, and then complain about corruption in

government.

Responsibility

Again, most people want to be free to do the things (to explore, etc.) but they are afraid of failing. The fear of failure is manifested in irresponsibility, and especially in delegating those personal responsibilities to others where success is uncertain or carries possible or created liabilities (law) which the person is not prepared to accept. They want authority (root word - "author"), but they will not accept responsibility or liability. So they hire politicians to face reality for them.

Summary

The people hire the politicians so that the people can:

- (1) Obtain security without managing it.
- (2) Obtain action without thinking about it.
- (3) Inflict theft, injury, and death upon others without having to contemplate either life or death.
- (4) Avoid responsibility for their own intentions.
- (5) Obtain the benefits of reality and science without exerting themselves or learning either of these things.

They give the politicians the power to create and manage a war machine:

- (1) Provide for the survival of the nation/womb.
- (2) Prevent encroachment of anything upon the nation/womb.
- (3) Destroy the enemy who threatens the nation/womb.
- (4) For the sake of stability of the nation/womb, destroy those citizens of their own country who do not conform.

Politicians hold many quasi-military jobs, the lowest being the police who are soldiers, the attorneys and C.P.A.s next who are spies and saboteurs (licensed), and the judges who shout orders and run the closed union military shop for whatever the market will bear. The generals are industrialists. The "presidential" level of commander-in-chief is shared by the international bankers. The people know that they have created this farce and financed it with their own taxes (consent), but they would rather knuckle under than be the hypocrite. Thus, a nation becomes divided into two very distinct parts, a docile sub-nation [great silent majority] and a political sub-nation. The political sub-nation remains attached to the docile sub-nation, tolerates it, and leaches its substance until it grows strong enough to detach itself and then devour its parent.

System Analysis

In order to make meaningful computerized economic decisions about war, the primary economic flywheel, it is necessary to assign concrete logistical values to each element of the war structure - personnel and material alike. This process begins with a clear and candid description of the subsystems of such a structure.

The Draft (military service)

Few efforts of human behaviour modification are more remarkable or more effective than that of the socio-military institution known as the draft. A primary purpose of a draft or other such institution is to instil, by intimidation, in the young males of a society the uncritical conviction that the government is omnipotent. He is soon taught that a prayer is slow to reverse what a bullet can do in an instant. Thus, a man trained in a religious environment for eighteen years of his life can, by this instrument of the government, be broken down, be purged of his fantasies and delusions in a matter of mere months. Once that conviction is instilled, all else becomes easy to instil.

Even more interesting is the process by which a young man's parents, who purportedly love him, can be induced to send him off to war to his death. Although the scope of this work will not allow this matter to be expanded in full detail, nevertheless, a coarse overview will be possible and can serve to reveal those factors which must be included in some numerical form in a computer analysis of social and war systems. We begin with a tentative definition of the draft. The draft (selective service, etc.) is an institution of compulsory collective sacrifice and slavery, devised by the middle-aged and elderly for the purpose of pressing the young into doing the public dirty work. It further serves to make the youth as guilty as the elders, thus making criticism of the elders by the youth less likely (Generational Stabilizer). It is marketed and sold to the public under the label of "patriotic = national" service.

Once a candid economic definition of the draft is achieved, that definition is used to outline the boundaries of a structure called a Human Value System, which in turn is translated into the terms of game theory. The value of such a slave labourer is given in a Table of Human Values, a table broken down into categories by intellect, experience, post-service job demand, etc. Some of these categories are ordinary and can be tentatively evaluated in terms of the value of certain jobs for which a known fee exists. Some jobs are harder to value because they are unique to the demands of social subversion, for an extreme example: the value of a mother's instruction to her daughter, causing that daughter to put certain behavioural demands upon a future husband ten or fifteen years hence; thus, by suppressing his resistance to a perversion of a government, making it easier for a banking cartel to buy the State of New York in, say, twenty years.

Such a problem leans heavily upon the observations and data of wartime espionage and many types of psychological testing. But crude mathematical models (algorithms, etc.) can be devised, if not to predict, at least to predetermine these events with maximum certainty. What does not exist by natural cooperation is thus enhanced by calculated compulsion. Human beings are machines, levers which may be grasped and turned, and there is little real difference between automating a society and automating a shoe factory. These derived values are variable. (It is necessary to use a current Table of Human Values for computer analysis). These values are given in true measure rather than U.S. dollars, since the latter is unstable, being presently inflated beyond the production of national goods and services so as to give the economy a false kinetic energy ("paper" inductance). The silver value is stable, it being possible to buy the same amount with a gram of silver today as it could be bought in 1920. Human value measured in silver units changes slightly due to changes in production technology.

Factor 1 - Enforcement

As in every social system approach, stability is achieved only by understanding and accounting for human nature (action/reaction patterns). A failure to do so can be, and usually is, disastrous. As in other human social schemes, one form or another of intimidation (or incentive) is essential to the success of the draft. Physical principles of action and reaction must be applied to both internal and external subsystems. To secure the draft, individual brainwashing/programming and both the family unit and the peer group must be engaged and brought under control.

Factor 2 - Father

The man of the household must be housebroken to ensure that junior will grow up with the right social training and attitudes. The advertising media, etc., are engaged to see to it that father-to-be is pussy-whipped before or by the time he is married. He is taught that he either conforms to the social notch cut out for him or his sex life will be hobbled and his tender companionship will be zero. He is made to see that women demand security more than logical, principled, or honourable behaviour. By the time his son must go to war, father (with jelly for a backbone) will slam a gun into junior's hand before father will risk the censure of his peers, or make a hypocrite of himself by crossing the investment he has in his own personal opinion or self-esteem. Junior will go to war or father will be embarrassed. So junior will go to war, the true purpose notwithstanding.

Factor 3 - Mother

The female element of human society is ruled by emotion first and logic second. In the battle between logic and imagination, imagination always wins, fantasy prevails, maternal instinct dominates so that the child comes first and the future comes second. A woman with a newborn baby is too starry-eyed to see her child as a wealthy man's cannon fodder or a cheap source of slave labour. A woman must, however, be conditioned to accept the transition to "reality" when it comes, or even sooner. As the transition becomes more difficult to manage, the family unit must be carefully disintegrated, and state-controlled public education and state-operated child-care centres must become more common and legally enforced so as to begin the detachment of the child from the mother and father at an earlier age. Inoculation of behavioural drugs [Ritalin] can speed the transition for the child (mandatory). Caution: A woman's impulsive anger can override her fear. An irate woman's power must never be underestimated, and her power over a pussy-whipped husband must likewise never be underestimated. It got women the vote in 1920.

Factor 4 - Junior

The emotional pressure for self-preservation during the time of war and the self-serving attitude of the common herd that have an option to avoid the battlefield - if junior can be persuaded to go - is all of the pressure finally necessary to propel Johnny off to war. Their quiet blackmailing of him are the threats: "No sacrifice, no friends; no glory, no girlfriends".

Factor 5 - Sister

And what about junior's sister? She is given all the good things of life by her father, and taught to expect the same from her future husband regardless of the price.

Factor 6 - Cattle

Those who will not use their brains are no better off than those who have no brains, and so this mindless school of jelly-fish, father, mother, son, and daughter, become useful beasts of burden or trainers of the same.

Please note that the section of text above, shown in blue, is not an expression of my own personal opinion, but comes from an anonymous document. However, sections of it describe clearly what is without question being applied to the people in many nations of the world today, so it is difficult to discount any of what is said. At the present time, economic warfare is most definitely being waged against normal, innocent people in most countries of the world, and there is every appearance that a major offensive against us is in progress, instigated and orchestrated by the few "Elite" New World Order people who have already caused so much unnecessary death and suffering.

So who are the New World Order people whose aims are to disadvantage and destroy ordinary people through their "Quiet War"? Well, there are several major branches of them, each presenting a benign and caring face to the world and most with large numbers of sincere adherents who have not the slightest idea of the aims and policies of the few people at the top who actually direct and control those organisations. While most operations are carried out in complete secrecy, the most visible people in the ruling bodies form the Bilderberg Group. This comprises 13 Freemasons, 13 Vatican representatives, and 13 Black Mobility people. These 39 people of the Bilderberg Group have offices in Switzerland (the only European country which was never invaded or bombed during World War One or World War Two) answer to the 13 people who form the Policy Group, which in turn answers to the 9 people of the Round Table. The individuals concerned are typically, powerful financiers, industrialists, statesmen and intellectuals.

The power and influence of these people should not be underestimated. They have infiltrated and subverted the US Congress and Senate, rendering ineffective the checks and balances intended when the Constitution was originally set up. At 3:30 am on Saturday 4th August 1990, a minority of US Senators, maybe ten at most, passed the Senate Intelligence Authorisation Act for Fiscal Year 1991 (S.B. 2834). This bill is not widely known. It was brought to a vote by Senator Sam Nunn in the dead of night when the opposition was gone. It effectively transfers most authority of the United States Government directly into the hands of the President. It gives him the power to initiate war, appropriate public funds, define foreign policy goals, and decide what is important to US national security. It gives the President the power to initiate covert actions (a power never before given to any President) and prevents Congress from stopping the President's initiation of covert actions. It allows the President to use any federal "departments, agencies or entities" to operate or finance a covert operation. It empowers the President to use any other nation or private contractor or person to fund or operate a covert action. It redefines covert actions as operations "necessary to support foreign policy objectives of the United States" which is a definition which is so broad and vague as to be essentially unlimited. It, for the first time ever, officially claims the right of the United States to interfere secretly in the internal "political, economic or military affairs" of other countries in direct and flagrant violation of international law. It requires the President to prepare and deliver a written finding to the Intelligence committees of Congress, but it allows the President to omit "extremely sensitive matters" and authorises the President to claim Executive Privilege if Congress asks too many questions.

Further, there are no penalties in the Bill for violating any of its provisions, including the provision for requiring a finding. That Bill effectively handed all the powers of government to the President, effectively making him the sole ruler of the USA without accountability to anyone.

I suggest that the New World Order people have sufficient influence to ensure that every candidate for President of the USA is a member of the New World Order. That way, they are assured that they have full control of the whole of the USA at all times no matter what the outcome of the "democratic" voting. It is said that Henry Ford stated that customers could have a new Model T car in any colour they wanted, provided that the colour was black. Well, the equivalent is now in place, where the American people can have any President they want, provided that the President is a New World Order man. This information is not even considered secret any more. For example:

"... Some even believe we (the Rockefellers) are part of a secret cabal working against the best interests of the United States, characterising my family and me as 'internationalists' and of conspiring with others around the world to build a more integrated global political and economic structure - one world, if you will. If that's the charge, I stand guilty, and I am proud of it. "

—David Rockefeller, *Memoirs* (2002, Random House publishers), page 405

It should not be imagined that the events in the USA have no effect elsewhere. The New World Order people are working on expanding the EU, blurring the identities of individual countries through legislation, reducing the effects of borders and generally moving towards a single entity with one central government. They are actually aimed at producing ten unified areas of the world which they then intend to amalgamate into a single world state governed by them. This is judged to be easier if there are fewer people, so one of their major aims is to reduce the number of people living at the present time. They also need the remaining people to be wholly dependent on them for the essentials of life, which is one reason why they oppose the introduction of any free-energy device, since having an independent source of power would put people outside their direct control and so will not be allowed.

If the video has not been wiped off the web, then the video from Walter Burien:

<http://video.google.com/videoplay?docid=6703413885850200097&hl=en> demonstrates the double-bookkeeping which is being operated by the US government where the US people are being told that they are in debt when in fact, "public" funds are massively in profit. In Britain, and probably in many other places in the world, nearly 80% of all earned income is taken away from ordinary people. Natural rights are being done away with and replaced by "privileges" which can be revoked. It has been remarked with considerable insight, that "in the old days, slaves were housed and fed, but today, those slaves are expected to house and feed themselves". For a simple straightforward explanation of how this is done, try <http://www.yourstrawman.com>.

Chapter 16: Questions and Answers

This is a fast-moving field of research and development, and one where a single person working alone, can outperform research establishments with unlimited budgets and many staff members. If you believe that the answers given below are inadequate or incorrect, then please tell me as this is definitely a learning process for all of us.

Topic: What To Build

I am regularly asked to recommend a device for someone to build. This is an impossible task as the person asking never says in which part of the world he lives, how much money could be used in the project, what tools are to hand, what workshop space (if any) is available, what local supplies of materials is like, whether the home is in a city or an isolated remote place, local assets like a shoreline, a fast-flowing stream or lots of sunshine all year round, how much ground space is available, what his skills are, etc. etc.

What should be realised is that a small group of friends can achieve a great deal. If one person likes working with engines and another can fix television sets and a third can weld, or ... whatever. By working together, they can achieve a great deal and benefit both themselves and their friends, not to mention having a good deal of fun in the process and ending up with a great sense of achievement.

We should not dismiss the various forms of renewable energy such as wave power, RAM pump, solar panels, wind power, biomass and the like. Granted, they do not always provide power all of the time, but if they provide most of the power you need for most of the time you need it, then that can be a considerable saving on your present power costs, so you should consider the devices covered in chapter 14. One possibility is to use a RAM pump with a fast-flowing stream, to pump water up into a water tower over night, and use the tank of water to power a turbine driving an electrical generator when needed.

Diagram from: www.thefarm.org/charities/i4at/lib2/hydrpump.htm

If you have the space and the sunshine, then a parabolic mirror can focus the sunshine, produce steam and drive a generator, a mechanical drive, a pump, or whatever else is needed.

Above: Steven Vanek with his machine which uses solar thermal energy to make ice.

If you are lucky enough to have access to a small section of coastline, then using either wave power or tidal power gives a major amount of power each year with even a simple low-tech construction like this:

It is not necessary to "go for broke" and aim at a device which will completely do away with your power needs for evermore. Initially, it can be a major step forward to produce a device which reduces your energy bill by a good deal and later on, progress to an additional system which makes you fully independent of others. For example, it is perfectly possible to drive a RotoVerter (chapter 2) with a solar panel:

The output is much more powerful than the input from the solar panel and can be used to run power tools, charge batteries or perform other useful tasks at effectively no cost at all.

The Frenette heater (chapter 14) does give significant heat output for the modest power input needed to spin the central shaft. It is a simple construction well within the capabilities of most people, and it could be driven by a solar panel if you live in an area where it is cold and sunny. As the array of discs spin, the vegetable oil inside the cylinder gets heated and pushed upwards and outwards, flowing through the radiator tubing, heating the house:

There are many high-performance alternatives which need special skills or equipment to build, but these can be found and constructed by those people who have above average skills and workshop facilities.

Devices which can provide power at any time, and at any location, include running a standard electrical generator with water as the only fuel (chapter 10). Strictly speaking, the generator runs on energy drawn from the environment and not on water.

While it is perfectly possible to run this type of generator with water as what appears to be the only fuel, it must be realised that a generator of this type produces noise which will not be acceptable for neighbours if the user lives in a congested city environment. Admittedly, a suitable housing with many carpet-covered baffles would allow good air flow and cooling while reducing the noise to very low levels, but generally speaking, this is a solution for people who like working with internal combustion engines and who live some distance away from other people.

The Adams motor (chapter 2) when accurately built, can produce eight times as much output power as the power needed to make it operate. This is a good energy gain and the device is not difficult to build:

Another device which is not hard to build is the Charles Flynn magnet motor (chapter 1):

And if the electronics used to drive it is something which you have not come across before, then chapter 12 shows you how to understand and make these kinds of electronic circuits. A friend who is familiar with circuitry might help. A motor of this type can be made to produce any amount of power. Flynn's prototype ran at 20,000 rpm driven by just an ordinary 9-Volt dry cell battery. A big advantage with a motor like this is that you understand exactly how it works, and as you built it in the first place, if it ever breaks down, then you can fix it.

Another possible simple project is the Kundel magnet motor (chapter 1). Using just a simple rocking arm movement, powerful shaft rotation is produced. That rotation can be used as a mechanical drive, or to spin magnets past wire coils to produce electricity:

This motor operates by moving the magnets on the rocker arms, away from the rotor magnets when they would oppose the rotation and closer to the magnets on the next rotor which would promote the rotation. The rate at which the loudspeaker cone electromagnet is driven by an electronic circuit, controls the speed of the motor.

Another device which can supply extra power is John Bedini's pulsed flywheel (chapter 4). The objective is to apply a pulsed drive to a heavy flywheel. Each pulse acts as an impact, providing excess power to the flywheel. John had a small one of these running in his workshop for more than three years.

The DC motor is pulsed by a simple electronic circuit and the flywheel spins permanent magnets past a circle of coils of wire. The voltage generated in the coils is converted with four diodes to produce a pulsing DC voltage which can charge the battery and do additional work as well.

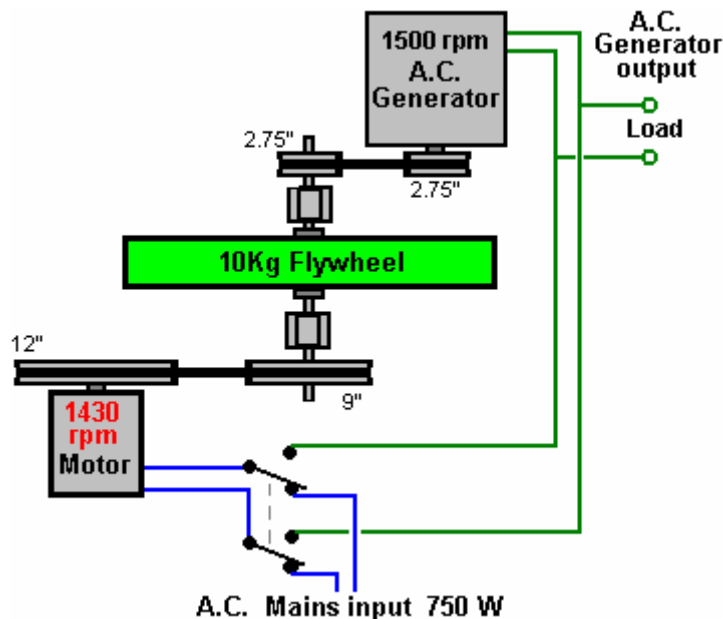

The output from a device of this nature depends on the size of the device. Jim Watson built one which was twelve feet high and he got 12 kilowatts of excess power from it. Obviously, I would not suggest that you build one as big as that, but perhaps one of say, three feet in diameter might have a very useful output. You have the option of wiring the coils in a chain in order to have a higher voltage output. If you do that, then have the same number of coils as permanent magnets so that they all pulse at the same moment. Alternatively, if you want to use magnets mounted with every second one having a different pole facing outwards and still have the coils in a chain, then have twice as many magnets as coils.

A similar wheel-pulsing method is used in the water-jet generator (chapter 4) which looks like a very simple thing to implement. Here, a jet of water provides a jerky drive to a wheel when the jet of water hits paddles attached to the rim of a wheel, geared through to an electrical generator.

<http://www.youtube.com/watch?gl=GB&hl=en-GB&v=zlinM1wAl5U> has a video showing this arrangement in operation. If you decide to build it then please arrange for an external change-over switch located in a dry area outside the box for switching the pump over from the mains supply to the output from the generator as that is not something which should be done with a plug and socket in a wet area.

One of the most straightforward projects would be replicating Chas Campbell's flywheel system. Perhaps an arrangement like this:

Or if you prefer, an arrangement where there is more than one flywheel, again, keeping the flywheel shaft input drive pulley larger than the output pulley on that shaft.

Moving to a somewhat more difficult, but quite possible project. Dr Scott Cramton's version of Dave Lawton's electrolyser (chapter 10) is capable of generating a serious HHO gas output of 6 litres per minute of high quality gas for a very small power input.

This project needs patience as each of the tubes needs to be filed down so that they all resonate at the same frequency. Some minor electronics needs to be built and the pipes either conditioned or alternatively, insulated. The gas output can be used for heating, welding, cutting, cooking, boosting a vehicle or running a generator on water.

If you decide to start some project, then whatever project you pick, the most important thing is that it should be one which interests you and building it is fun. You will notice that the projects suggested here generally have moving parts which make it easy to see how the device is operating. The more difficult projects where there are no moving parts and meters need to be used can be left for a later time. If you decide to build something, then let me wish you good luck with your project.

A Matter of Opinion

This eBook is just a sharing of the information which I have come across during some years of investigating devices which are loosely described as being “free-energy” devices – a description which some people dislike because it costs money to construct or purchase a device which can produce useful work, even if the device appears to be self-powered. I am not an expert in the subject and so I have attempted to present the information in a direct and factual way.

However, I am regularly asked for my opinion on various devices and which one is best suited to some particular person, so, reluctantly, I will share some personal opinions on a selection of devices. Please understand that the following is just my opinion and could very well be completely wrong. Your level of interest in any particular device depends on your background and whether you are interested in a small device which proves that free-energy exists and can be harnessed, even though the output level is very small. Or if your objective is to obtain a device which can reduce your expenses. Or if you just want to investigate the subject for the sake of general interest. So, we have a wide range of different devices and a range of possible interests, so an attempt has been made to divide the devices into categories based on ease of construction and the output power levels produced by each device.

Please bear in mind that there has been a very high level of opposition to any of this type of information becoming well-known and so, information on each device tends to be limited, and while half a dozen devices may well be offered for sale in 2013, at the present time few are commercially available, leaving you to build your own or get a friend to join with you in the construction, which is actually a very good idea as small groups of people can have a very wide range of skills.

Devices Which are the Easiest to Build

[The Magnetic Frame of Lawrence Tseung](#) (chapter 3)

[The Transformers of Thane Heins](#) (chapter 3)

[Stephan Leben's adaptation of the Flynn Magnetic Frame](#) (chapter 3)

These three devices have no moving parts and their performance has to be determined by measurements of the input power and the output power. They all operate by passing a fluctuating magnetic field through a frame, which is typically made from thin strips of laminated steel. These devices are limited in their power levels by the amount of magnetic flux which can be carried by their magnetic frames, and to a much lesser extent, by the maximum current which can be carried by the coil windings placed on those frames. Once the core reaches magnetic saturation, applying a stronger magnetic field to it has no effect at all and just wastes the additional power. So, in order to get any form of powerful output, the magnetic frame or core needs to have a high magnetic capacity, which typically means that the frame has to be big, which in turn, means it will probably be heavy and it may be expensive. Using specialised materials for the core could make a major difference, but most constructors will not have access to any of these nanocrystalline materials.

When properly constructed and operated, these devices can certainly show you that $COP > 1$ is definitely possible. However, as the results are based on measurements, it is generally difficult to convince anyone else as many people will presume that you are operating a hoax as they have always been taught that any such operation is "impossible" as there is no such thing as "a free lunch". If you do want to comment on the input and output power levels, then be sure to measure the DC voltage and the DC current on both the input and the output as it will be argued that any form of waveform will give measurement errors.

The most convincing thing is if the device supplies it's own input power as well as supplying some additional item, even a single LED. Where the COP is greater than 1, this should be possible, but to keep the device operating steadily, I suggest that you use a voltage-stabilised circuit to supply the input power as that prevents a runaway situation where increased output power produces increased input power and a positive feedback is created which could lead to the almost instant destruction of circuit components which have been driven well past their rated values.

[Clemente Figuera's Split Transformer](#) (chapter 3)

The Figuera split transformer is exceptional in that it is completely free of the usual crippling Lenz-Law effects and it has the capability of outputs of several kilowatts. The details have been lost for more than a century and only recently been made available, so considerable experimentation is needed but the possible results are spectacular. If electronics does not appeal to you, then using mechanical switching like Clemente did, is a perfectly feasible method of construction. If you want to supply the input power from part of the output, then I would recommend using a stabilised power supply to ensure that only your chosen voltage is supplied as input power.

[Carlos Benitez's Generator](#) (chapter 5)

This spectacular design is capable of kilowatts of continuous excess power through the use of just two batteries. The design documentation explains how to calculate the size of the components and the mechanical switching is only used very occasionally and so can be replaced with simple solid-state switching to avoid mechanical construction.

[Lawrence Tseung's "FLEET" Toroid](#) (chapter 5)

This is a very easy device to construct and use, but it's output power is very small. Demonstration kits are due to be offered for sale quite soon. Developments are in hand and I have been told of a version which can run at six kilowatts. The presently known versions appeal enormously to many people who are intrigued that an almost totally exhausted single dry cell battery with far less than one volt, can charge a 6-volt battery or light LEDs for long periods. While this is definitely a 'fun' device, it is unlikely to convince anyone that 'free-energy' exists. A one-kilowatt version would be a very different matter. I have confirmed $COP > 1$ operation by using one 12V battery to charge another, swapping the batteries over and repeating the process. The result was that both batteries ended up with considerably more genuinely useable power.

[The Aerial Plate System](#) (chapter 7)

This is also very easy to construct and being a modular system it has the advantage that it can easily be expanded to give substantial power outputs. This device is based on a Nikola Tesla invention and it has nothing to do with radio transmissions as it picks up ambient energy from the environment. While it can be used to charge batteries, it might also be used for direct power supply if suitable control circuitry is constructed for it. It needs a very high aerial and an extremely good earth in order to perform properly.

[John Bedini's Simple School Girl Battery-pulser](#) (chapter 6)

[Alexkor's Solid-state battery-pulsers](#) (chapter 6)

These devices can be very effective in what they do but they are not likely to convince anyone of $COP > 1$ operation. Ron Pugh of Canada has achieved $COP = 13$ with his implementation of the Bedini device running on 24-volts. It is difficult to demonstrate the actual performance as batteries are capable of getting a false "surface charge" which shows a high voltage but does not indicate a genuinely high level of recharging for that battery as the voltage will drop rapidly when driving a load. The only reliable way to assess the state of charge of a battery is to make it drive a load and observe how long it can sustain that load. The most recent, very-simple, solid-state Alexkor circuit has a $COP = 12$ performance.

The Bedini pulse-charger has an impressive spinning wheel or rotor, but its usefulness is severely limited as it can only charge batteries which are not being used to power a load. That means that its charged batteries are only occasionally available, or two sets of batteries are needed, one for use while the other set is being charged. Ordinary batteries are not all that useful as their life is severely shortened if they are discharged in less than a 20-hour period.

[Joseph Newman's Motor](#) (chapter 11)

This is a particularly easy device to build and one which had an experienced technician considerably bothered by its performance (as shown in Joseph Newman's book which can be downloaded from <http://www.free-energy-info.tuks.nl/>) as he could not explain how it could possibly perform as it does. However, the amount of power from any reasonably-sized replication will be low.

[Internal Combustion Engine Boosters](#) (chapter 10)

Simple boosters such as the "Smack's Booster" can be built quite easily and they can improve the burn quality of the standard fuel used in an internal combustion engine very considerably, reducing the unwanted emissions and raising the mpg figures by a typical amount of 20% to 40%. While building and using a booster, the actual installing of one in a vehicle does require some basic vehicle knowledge and a few basic tools.

[Dietmar Hohl's Magnet Motor](#) (chapter 1)

This motor has been replicated and proven to work. Given a little care when constructing it and angling the stator magnets as shown gives a considerable improvement in the power available. However, as shown with just one V-set of magnets and one cylinder of stator magnets, the power is not that great although it demonstrates conclusively that permanent magnets can be used to provide power and demonstrate "perpetual motion" which is so much feared by "scientists" because it shows that their pet theories are, at best, incomplete and at worst, completely wrong. To get some power from this motor design, you need to use a larger diameter drum with two, three, four or five sets of V-magnets around its circumference, and possibly more than one set of magnets along the length of the drum. The number of magnets involved in even the minimum arrangement is quite large.

[Ben Teal's Motor](#) (chapter 1)

This motor design is very, very simple and the first version was built using wood and it proved to be very effective, having a two-inch (50 mm) diameter drive shaft. Ben found that he was unable to slow or stop the motor by grasping the drive shaft as the motor was just too powerful. This motor has not been shown to be $COP > 1$ but I wouldn't be surprised if it is.

[Don Kelly's Magnetic Motor](#) (chapter 1)

I have never heard of anybody building this design. It has the potential for serious $COP > 1$ operation as the driving power comes from the magnets and only a small amount of power is needed for the motors to move the stator magnets. I see synchronising the motors as being a potential problem and so would suggest that using only one motor to drive all of the stators as being a sensible option. The motor speed during start-up can be controlled manually with a DC Motor Speed Controller and then the setting just left when it is running at full speed. It could be used to drive sets of magnets between coils to generate electricity and that output boosted substantially further with the coil-shortening method described in chapter 2.

[Stephen Kundel's Magnetic Motor](#) (chapter 1)

This is a very simple and direct method of getting permanent magnets to provide continuous drive with just a very low electrical input used to change the location of the stator magnets in much the same way as in Don Kelly's motor design. The movement is very simple as it is just a rocking movement, driven by the mechanism used in a loudspeaker. As there can be as many sets of rotor and stator magnets on any drive shaft, the power of this design can be substantial.

[Raoul Hatem](#) (chapter 2)

This arrangement of magnets and generators is expensive as each generator uses thirty-six powerful magnets to give good magnetic coupling between the drive motor and every generator. Some people believe that this design cannot possibly be $COP > 1$ as the motor drives each of the generators (although most are driven indirectly). I don't know if that is correct or not, but there is the possibility that as the motor creates a rotating magnetic field

whether or not there are any generators there at all, it may be that the fact that a nearby generator happens to use that rotating magnetic field to rotate its armature, has little effect on the drive motor. Certainly, Raoul didn't keep buying and adding extra generators if he was not getting any benefit from them. This arrangement has the potential of serious power gains, but it would be fairly expensive to investigate if that is indeed the case.

[John Bedini's pulsed flywheel](#) (chapter 4)

[Lawrence Tseung's pulsed flywheel](#) (chapter 4)

These are definite winners. Jim Watson built a monster size version of John's which was self-powered and had 12 kilowatts of excess power. Lawrence Tseung's prototype is only low power but it demonstrates $COP > 1$ very clearly indeed on only one set of rotor magnets. The design performance should be dramatically increased by using several sets of rotor magnets as that would raise the power levels considerably. This is a very easy home-build project requiring very little in the way of constructional skills or specialised tools.

[Lawrence Tseung's Impact Gravity Wheel](#) (chapter 4)

This is a device which has been replicated and it too demonstrates the "impossible" perpetual motion so feared by our revered "scientists". It requires minimal skills to replicate and the components are all low-cost. Definitely and interesting project to build and investigate and one which has the potential of power generation without the need for any form of input power or fuel.

[The Nudged-weights Design of Mikhail Dmitriev](#) (chapter 4)

This is a design which I have only encountered very recently and it has major potential. It does with weights, what designs like Kundel and Kelly do with magnets. Energy is extracted from the gravitational effect (if you will pardon the expression) as weights are pushed downwards. The lever arm for those weights is longer than the lever arm when they are being lifted upwards again, and that gives a continuous turning force. The increased lever arm for the falling weights is caused by a small electric motor giving them a nudge away from the rotor axle. Before the weight has time to swing back into its vertical position its rotor pivot has reached the bottom of its travel. In some of his designs, Mikhail just allows the weight to swing freely and in other designs he uses an angled ramp to control and limit the positioning. The brief presentation in chapter 4 shows tiny weights, but even for a first-time home-build replication, there is no reason why the weights should not be substantial. They can be suspended and given a ball or roller bearing suspension and the motor can have broader strips which press directly on the rectangular body of the weight. Mikhail is thinking of marketing ready-built units providing 6 kilowatts or more of electrical power, and plans and kits as well. The rotor turns slowly and powerfully and so need to be geared up to increase the speed for electrical generation.

[The Gravity Wheel Design of Abdulsalam Al-Mayhi](#) (chapter 4)

This device is very simple to build, being entirely mechanical and requiring no complicated parts. It is essentially, a wagon wheel with spokes which have sliding weights on them. If the style of construction shown in chapter 4 is used, then please be aware that a large number of roller bearings are needed. It has been suggested that spokes which have a square cross-section rather than round as shown, might be an advantage.

[Chas Campbell's Pulsed Flywheel](#) (chapter 4)

This is a good design for people who do not want to get involved in electronics as it uses standard mechanical components and an off-the-shelf motor and generator. I don't know of anyone who has replicated this design, but since nobody has any particular reason to tell me about what they have done, that does not mean anything much. The potential for excess output power is high although Chas has not made any output power measurements.

[James Hardy's Water-jet Generator](#) (chapter 2)

This device is both patented and shown on video on the web. It is very, very simple in concept and should be easy to build. Unlike the video demonstration, a proper working model is wholly enclosed and fairly quiet in operation. It is self-powered and has significant excess electrical power. Construction is very straightforward and uses readily available off-the-shelf components.

[The Robert Adams Motor/Generator](#) (chapter 2)

If built without paying any attention to the essential details, this design will operate but always be $COP < 1$ in spite of the design having an extremely high potential. If care is taken with the construction and high voltage used and the timing adjusted to its optimum settings, then an input of just 27 watts has been shown to produce 32 kilowatts of power, capable of running a household or office. Adjustments for optimum performance will take time and patience and this design is more suited to people who have some understanding of electronics.

[Pyramids](#) (chapter 9)

The usefulness of a pyramid depends to a considerable degree on how sunny the local environment is. The bulk of the energy which they concentrate flows from the sun, so sunny areas have a much higher pyramid effect than dull areas where direct sunlight rarely reaches the ground. A pyramid is not particularly difficult to construct if you have the dimensions, but size is very important with increased size having a disproportionate effect. In this area, bigger is definitely better. Covering the pyramid with gold-plated iron is the optimum, but many other much

cheaper materials can be used very effectively. Pyramids are probably better used to enhance growth and for health improvement purposes rather than for generating electrical power.

[The Tesla Coil and Grounded Plate](#) (chapter 5)

This method for extracting substantial power was disclosed by Nikola Tesla and has been demonstrated in broad outline on video by Don Smith, although he did not demonstrate equipment being powered by the electrical energy generated. A standard Tesla Coil (available commercially) directed on to a metal plate or two-plate capacitor which is connected to an effective earth wire, can supply serious amounts of electrical power. Nobody seems to be interested in using this method to generate excess energy and it is not at all obvious why that should be.

[Art Porter's Magnet Motor](#) (chapter 2)

This is a variation of the Charles Flynn motor where an electromagnet coil is used to modify the magnetic field of a permanent magnet. Art states that he gets a 2.9 times improvement in the field strength doing this and he uses it to operate a reciprocating motor. Instead of having mechanical movement, it seems as if it would be more effective to use that magnetic field alteration to generate electricity in a stationary coil as that seems likely to give a COP>1 performance and the currents used could easily be high, giving substantial excess output power. It should be perfectly possible to have a whole bank of these magnet/coil combinations in a single device.

Devices which are of Medium Difficulty

[Charles Flynn's Magnet Motor](#) (chapter 1)

This design is powered by permanent magnets which are intermittently shielded by electromagnet windings. As the construction of those windings depends on the voltage being used to drive them, the spacing between the magnets and the strength of the actual magnets used in the construction, experimentation needs to be undertaken before the final construction and assembly is undertaken. An understanding of basic electronics is needed. The power and speed of the motor are exceptional. The input power needed for the prototype described by Charles is very low with just an ordinary 9-volt dry-cell battery being able to power the motor at 20,000 rpm. If the motor is used to drive a generator (whether home-built or commercial), there does not appear to be any reason why the input power should not be provided by a voltage-stabilised power supply driven by the output, making this a self-powered system which can power other electrical equipment or a mechanical load.

[Electrical Generator Running on Water](#) (chapter 10)

As far as power output is concerned, this is a major winner as it is both self-powered and provides kilowatts of excess electrical power. As so much electrical power is generated, the design of the electrolyser used should not be critical. While the generator spark timing can be delayed so that just HHO and cold water mist can be used, the David Quirey method of bubbling the HHO through acetone, allows an unmodified generator to be used, making the project very much more simple. This project is particularly suited to people who like maintaining, adjusting and tuning vehicles.

[The Pulsed Coil of 'UFOpolitics'](#) (chapter 3)

This is a design which generates cold electricity which can safely light a bulb under water. With no moving parts, the only (minor) difficulty is constructing the electronics to drive the coil. Running off 36V, this is a very interesting design for people who want to experience the remarkable effects of cold electricity.

[Bill Muller's Motor/Generator](#) (chapter 2)

Ron Classen has replicated this design and reached COP=2.2 after very considerable expenditure of time and money. You need excellent mechanical skills to be successful with this design although the coil-shortening technique might well raise the electrical output very substantially.

[The RotoVerter](#) (chapter 2)

This design involves running a 3-phase motor from a single-phase power supply. The capacitor tuning needed to do this depends on the loading of the output unless Phil Wood's method of adding in a DC motor is used. This project mainly requires mechanical skills rather than out and out electronics. This arrangement is best suited to where an existing motor is used extensively and under those circumstances, the cost of running the original motor can be reduced substantially by the RotoVerter system and the system can be run on a solar panel used with an inverter.

[Richard Willis' Motionless Generator](#) (chapter 3)

[Silverhealthu's adaption of the Willis Generator](#) (chapter 3)

Richard has shown his generator on the US version of The Dragon's Den television programme and he has offered his "Magnacoaster" generators for sale. I understand that the technical problems initially encountered have now been overcome and so units should be shipping at this time. The simplified 'silverhealthu' version

should not have any problems when run at reasonable power. These devices are a starting point for experimentation and they are best suited to people who have some knowledge of electronics.

[Dan Davidson's Acoustic Generator](#) (Appendix)

[Pavel Imris' Optical Amplifier](#) (chapter 3)

These devices appear quite straightforward, but I have never heard of anyone actually attempting to replicate either of them. That being the case, they would need to be categorised as being designs which need further investigation if they are to be home-built.

[Dale Simpson's Hinged Plate and Gravity Wheel](#) (chapter 4)

[Murilo Luciano's Gravity Chain](#) (chapter 4)

These three devices have to be categorised as being untested designs and some people are of the opinion that they can't work. Until such time as they are built and tested, they have to remain as design ideas. The construction is not particularly difficult being mainly mechanical in nature, but there is no guarantee of success and it seems unlikely that the components could be easily used again in some other project.

[Dave Lawton's Hydroxy Cell](#) (chapter 10)

[Dr Scott Cramton's Hydroxy Cell](#) (chapter 10)

[Bob Boyce's Electrolyser](#) (chapter 10)

These three designs have very impressive performances, far outperforming Michael Faraday's efficiency results (which "scientists" believe are the maximum possible). For example, Bob Boyce's electrolyser design run on DC, can have efficiency results over 200% those of Faraday. Run on pulsed DC, the same electrolyser can reach 1,200% Faraday's maximum. The Lawton and Cramton cells, operating differently, also have outputs which are far in excess of Faraday's results. As more power is available from recombining the gas mix produced through burning when diluted with air and/or non-combustible gasses, or through use in an internal combustion engine, these devices represent considerable possibilities. However, the amount of work involved is not trivial and the use of the gas mix produced calls for ingenuity, so these are devices which have a high potential but they are not an instant-fix for anything.

[The Rosemary Ainslie Heater](#) (chapter 5)

This is a most interesting design which has COP=17. However, at the present time, power levels are so low that while it may be an interesting project and the principle is more than interesting, the output of this device is too low to provide any form of useful heating.

[Robert Patterson's Ram Wing](#) (chapter 10)

This is a simple physical device capable of improving the air flow around a moving vehicle to such an extent that it produces better mpg figures for the vehicle. Constructing one and mounting it on a vehicle is not a difficult task and the gains can be significant.

[Co-Axial Cable Electrets](#) (chapter 9)

This is a system which nobody seems willing to try. It involves baking a reel of co-axial (TV aerial) cable in an oven and allowing it to cool down very slowly. It is capable of supplying 10 mA at 10,000 volts which is a continuous power of 100 watts (better than most solar panels). The output energy from this passive device is drawn in from the surrounding environment. The high voltage of the output appears to put people off this device.

[The Colman / Seddon-Gillespie 70-year Battery](#) (chapter 3)

This is a device which has major potential and yet one which nobody seems interested in attempting to replicate. It is a small, compact, simple device which can provide one kilowatt of excess power for an estimated seventy years. Several of these in a single small housing could supply the electrical needs of a whole household. The materials used are not hazardous in any way and apart from some basic electronic circuitry and experimentation, there does not appear to be any problem with attempting to replicate it.

[Robert Krupa's "Firestorm" Spark Plug](#) (chapter 10)

This plug design is quite capable of giving improved fuel burn inside an internal combustion engine that the mpg performance can be increased very substantially and harmful emission drastically reduced. While Robert has a patent on his designs, he has not been able to find any manufacturer willing to make and sell Firestorm spark plugs. Prototypes have been made by getting a jeweller to modify a new set of standard spark plugs. This is expensive, but it is definitely something which is possible to do.

[Jesse McQueen's Self-powered System](#) (chapter 13)

On the surface, the patented proposal by Jesse appears to be impossible. However, as our understanding of how the various free-energy devices draw in environmental energy increases, some of the more impossible looking devices suddenly look as if they might actually be based on principles and methods which have been proven to work. Essentially, a battery powers a motor which spins a generator which keeps the battery charged and powers other devices. If both the motor and the generator are COP<1, then the system won't work. But, gearing is used

between the motor and the generator, and Chas Campbell has shown that with a flywheel in that linkage, additional power **is** actually available. It may be that Jesse does not mention the fact that his gearing linkage is heavy. It is interesting to note that the gearing that he specifies, has the correct ratio that Jacob Byzehr specifies in his patent for an energy gain through such linkage. It seems likely that Jesse has not disclosed all of the details in his patent. While constructing a test bed for this system should be easy if you have the components to hand, I suggest that you consider it to be an experimental investigation of his claims and don't expect immediate, spectacular results.

[Robert Tracy's Permanent Magnet Motor](#) (chapter 1)

This style of motor with magnetic shields being physically moved between pairs of magnets is probably one of the more difficult magnet motors to get operational. The main problem is getting an effective magnetic shield material. The expensive "mu-metal" material is supposed to be effective if it is fairly thick, but I am by no means sure that this is the case in actual practice. Screening powerful magnets with a passive material is not an easy thing to do and there are very few materials which seem able to do it. It might be possible to use a thin neodymium magnet as the 'shield' if it were orientated so that it was in repulsion mode for both the stator and rotor magnets as they approach each other. Because of the screening material problem, I could see the building of a Tracy prototype to be a lengthy experimental process in spite of the fact that the theory is perfectly sound.

Devices which require higher skill levels

[Muammer Yildiz's Permanent Magnet Motor](#) (chapter 1)

This motor has been demonstrated in a Dutch technical college and taken apart after the initial running was completed, showing that its operation was wholly genuine. However, some of the magnets used are of a tapered type which are probably not readily available unless ordered as a specially constructed batch which is generally an expensive way to buy magnets. Magnetic fields and their interactions and distortions are not the easiest things to understand or observe in a practical situation, and that makes the construction of permanent magnet only motors a difficult job. Howard Johnson and Mike Brady managed to make successful prototypes but then found it almost impossible to make others to that same design. So, if you decide to replicate Muammer's motor, please understand that it is not likely to be an easy thing to do.

[Michael Ognyanov's Self-Powered Power Pack](#) (Appendix)

This is a low power device intended to operate the lights on road traffic cones without the need for a battery. There should be no particular problem in building it if it were not for the need to cast a semiconductor block from a mixture of materials such as silicon, germanium, neodymium, gallium, etc. It seems likely that the average home constructor of devices is not geared up for melting and casting such materials, and so that puts it into the 'higher skills' bracket.

[Don Smith's High-frequency, High-voltage Devices](#) (chapter 3)

These devices appeal to a high percentage of interested people and yet they seem to be some of the most difficult to replicate. Admittedly, Don does say that he has not revealed all of the details on any one of his designs, but independent people have confirmed that doubling the voltage quadruples the output power and that additional electrical outputs can be produced from the fluctuating magnetic field without requiring any additional input power. Considering the limited success encountered by several people who have tried to construct replications, these devices have to be rated as some of the most difficult to get operational. Having said that, success has been achieved by putting two Tesla Coils back-to-back, connecting their secondary coils with a wire and taking the output from the larger diameter "L1" coil of the second Tesla Coil.

[Jerzy Zbikowski's Chain Drive](#) (chapter 4)

This device looks impossible, and yet it is reported to have been laboratory tested at COP=1.47 which is quite remarkable. As it is a mechanical chain drive, it requires good mechanical skills to construct the chain links and the two sprocket wheels. The mechanical operation needs to be high-quality, so it is unlikely that beginners to mechanical construction would have immediate success.

[The Magnetic Pendulum](#) (chapter 4)

While I don't know the name of the builder, this pendulum is reported to have been swinging continuously for more than two years now and while it does not appear to generate any useful power output, it is certainly an amusing project, especially should you want to show it to those people who say that 'perpetual motion' is impossible. It might well be possible to adapt it so that the magnetic push provided by dropping permanent magnets downwards near the end of the swing were provided instead by a coil which extracts power and then, when the current is cut off, generates the necessary push from the magnetic field generated by the back EMF. While the output power would be low, it would be very nice to demonstrate power generation with no input power being provided – just pure energy extraction from gravity and magnets (both of which are powered by the zero-point energy field).

[The Tesla Switch](#) (chapter 5)

This is one of the most difficult devices to get operational, in spite of the fact that it appeals to a large number of people. There are three possible modes of operation. If the diodes are turned the wrong way round so that they can feed current from each battery, then the operation will definitely be $COP < 1$ but it will be a good deal better than operating without the switch circuit in place.

The second way has only been achieved by John Bedini as far as I am aware. This is where the circuitry is the same but the circuit components and connecting wires are adjusted very carefully to produce circuit resonance. When that happens, the circuit becomes self-powering although there is little or no extra power for other devices.

The third way was developed and tested over three years by staff of the Electrodynne Corporation in America. In this version, the diodes are reversed and they only feed sharp voltage spikes back to the batteries, through the diodes which supposedly don't allow current to flow in that direction. This is a very different form of operation where the operating power flows into the circuit from the local environment. The batteries need to be 'conditioned' through long periods of being operated this way as the 'cold electricity' used in the circuit is the opposite of the 'hot electricity' which the batteries have been using up to now. This long conditioning period is generally enough to make the average builder give up and believe that the circuit just doesn't work. Dave Lawton was faced with exactly the same type of problem when he attempted to replicate Stan Meyer's "Water Fuel Cell". It appeared 'dead' and produced nothing during a whole month of testing, and then it suddenly burst into life, producing large amounts of HHO gas mix for almost no electrical input. Without his exceptional patience, Dave would never have succeeded. I believe that the same applies to the Tesla Switch when wired correctly with the diodes blocking current flow from the batteries – it is likely to take long-term and patient testing before the system swings into life.

One experimenter who did not believe the diodes could possibly work that way round, tested the arrangement and discovered that in spite of the theory, in practice, the reverse-biased diodes actually pass very sharp voltage spikes to the batteries, so the effect may well be like a slick version of John Bedini's battery pulsing circuits.

[Hermann Plauson's High-Power Aerial Systems](#) (chapter 7)

Hermann Plauson's patent which is in the Appendix, is so detailed and authoritative that it gives every indication that he is highly experienced in the actual design, construction and installation of serious aerial installations. He casually refers to "small" installations as being those of 100 kilowatt or lower capacity, so we are not talking about milliwatts here, although I understand that Hermann extracted somewhat under one kilowatt per aerial and used many aerials in any one installation. The difficulty with these types of system is that the input is very high voltage 'electrostatic' electricity, usually thought of as being useless for power generation. It is therefore, important to consider carefully the mechanisms which Hermann has in his patent for converting that power to ordinary electricity at normal voltage and current levels. We need to remember that Paul Baumann's "Thestatika" devices operate off this type of input power and yet put out kilowatts of mains electricity, so we know that it is perfectly possible. We do not have step-by-step building instructions for these types of system, and so they have to be rated as requiring more than the lowest skill levels. Also, many people are not located where they can erect a tall aerial, but remember that the Thestatika uses a Wimshurst style electrostatic generator rather than an aerial, so experimenters can work with a generator input. A.D. Moore's "Dirod" electrostatic generator seems like the most suitable home-build generator. It is described in detail in his book "Electrostatics – Exploring, Controlling and Using Static Electricity" Second Edition ISBN 1-885540-04-3 which is the only source for construction information on his generator.

[Frank Prentice's Ground Aerial System](#) (chapter 5)

Frank's design uses a one mile long wire supported just a few inches above the ground. He inputs a modulation signal of 500 watts and extracts 3 kilowatts of power. The information in his patent is not exactly overwhelming in its details, but the major obstacle is that very few people can install any such wire. It is not known if the wire could be run backwards and forwards over a small area, but if that were possible, then it would form a barrier against the normal use of that area. Frank didn't have that problem as he worked on railway tracks. The limited amount of information adds to the skill level needed to be successful with his design.

[Alfred Hubbard's Electrical Generator](#) (chapter 5)

This has a very high potential as it can put out substantial electrical power in spite of its simple construction. As it is based on just one section of the magnetisation graph where a small additional current produces a major rise in the magnetisation of the iron core, it will require careful adjustment and attention paid to the magnetic saturation levels of the materials used. It is very interesting that Joseph Cater's analysis of the device has spacings which match the recently discovered optimum tube spacings for the Joe Cell. I am not aware of anyone who has managed to replicate Alfred's device.

[Joseph Cater's Water-filled Generator](#) (chapter 5)

This looks like a really good design but it has the problem that it needs a transducer or klaxon running at 600 kHz and there does not appear to be any such transducer readily available on the market. The highest frequency I

have located was just 300 kHz which is clearly not suitable, so this design appears to be restricted to people who have skills which can design and construct a klaxon which can operate at 600 kHz.

[Joseph Cater's 'Orgone' Box](#) (chapter 9)

[The 'Joe Cell'](#) (chapter 9)

[The 'Nitro' Cell](#) (chapter 13)

In theory, each of these is capable of running a car engine without the need for any form of combustible fuel. I am aware of people who have succeeded in doing this with the Joe Cell and the Nitro Cell, but they both live in much sunnier locations than I do. These devices are some of the most difficult to get operational and it could well take a week for the car to absorb the cell influence before it can run without fuel. It has to be said that the technology involved in the operation of these devices has not been fully documented at this time and so is not fully understood and so experimenting with them is effectively a research project.

[Fuel-less Engines](#) (chapter 8)

These engines are perfectly viable but few people have the knowledge, skills, tools, workspace, inclination and time to go building or modifying an engine. These are Engineering tasks and not generally suited to 'back-yard' projects.

[The Searle-Effect Generator \("SEG"\)](#) (chapter 11)

According to John Searle, constructing just one of the many magnets needed for his generator requires more than a day of work and a million pounds in finance. This is enough to put most people off even considering his design. However, John certainly didn't spend anything like that amount of money when he built his first successful prototype, so we can probably ignore the quoted costs. Investigation would need to take place through the enthusiasts on John's forum and web site, but unless something has changed recently, it will probably take considerable research and subsequent thought in order to come up with a viable design for the construction of a useful generator or a flying disc.

[Michael Eskeli's 'No-Work' Turbine](#) (chapter 11)

Michael is clearly a gifted and very competent man who has many patents. In common with most gifted inventors, he does not excel in explaining and documenting his inventions and so a certain amount of background Mechanical Engineering knowledge would be of major help in understanding how to home-build one of his designs. The No-Work heating turbine in chapter 11 is a heater which only needs the friction of the bearings to be overcome by the motor spinning the turbine as the actual heating effect is 'free'. This is, of course, spectacular. If you happen to be a gifted individual and replicate Michael's turbine, then I would be most grateful if you would fill me in on suitable construction methods so that I could expand the description into a more detailed version which would encourage people to build one for themselves.

[William Hyde's 10 kW Electrostatic Generator](#) (chapter 11)

This involves the construction of a rotary generator with metal bodywork and so metalworking skills are needed (or somebody else with those skills needs to help out or be paid to do the work). The completed electrostatic generator has been patented and it is claimed to have an output of ten kilowatts of ordinary electricity, which makes it of serious interest to anyone needing to power a household. It is reputed to be COP=10 which means that the input power will be substantial for a large electrical output.

[Michael Faraday's Homopolar Generator](#) (chapter 13)

This design appeals to most people as it looks so simple. However, the problem is that most versions produce a very low voltage at very high current – potentially a thousand amps or more. Trying to come up with brushes which can carry high current for long periods of time without appreciable wear has proven to be a major problem. The Borderlands Science people discovered how to get an AC output from the device which allows the voltage to be stepped up and the necessary current reduced substantially. To date, I am not aware of anyone managing to produce a homopolar generator with a practical power input and output, but it is definitely a device which is wide open to experimentation.

[The Romag and Mini-Romag Generators](#) (chapter 13)

These designs call for construction with a range of different materials, and generally speaking, the materials used in any prototype are normally of major importance. Although these designs have been available for many years now, the only prototype which I have heard of is the 25 watt version built by J.L. Naudin, although there is probably not particular reason why the Romag could not be scaled up to produce a much larger output.

[Nikola Tesla's Generators](#) (chapter 11)

Neglecting the version which uses radium as that is probably difficult to obtain at the present time, the spark gap version is said to produce very substantial amounts of electricity while only using very simple components. I have never heard of anyone attempting to build one of these devices but in spite of the fact that we have limited information on the device, it seems like a very powerful unit which could well be extremely useful.

[The Jines Permanent Magnet Motor](#) (chapter 1)

This design includes magnetic shields and finding a suitable material for them might be a considerable problem. This design has to be considered to be fairly complicated due to the amount of mechanical work needed to construct the various mechanisms required for the motor.

[The Annis and Eberly Generator](#) (chapter 3)

This is a very clever solid-state generator. However, from the point of view of the home-constructor, producing their solid-state reluctance-switching material and it's controller would appear to be a major obstacle. Given that material and it's controller, many of the other devices would be exceptionally easy to build successfully.

[The "Carousel" Permanent Magnet Motor](#) (chapter 1)

This is a compact and very effective looking device but the very compact nature of it's construction probably makes it somewhat tricky to replicate. Anyone with good metalworking skills should be able to do it ok.

Devices which are unlikely to be practical

[The Ecklin-Brown Generator](#) (chapter 1)

People have had difficulty in making replications of this to work well. The biggest problem area is coming up with suitable magnetic screening material. It might be possible to adapt the design to use some of the very thin neodymium magnets instead of material which just screens the existing magnetic field. The Clemente Figuera design of chapter 3 is a better option.

[Howard Johnson's Permanent Magnet Motor](#) (chapter 1)

It appears that Howard has not been able to build replications of his original working prototype and while the theory is perfectly valid, that failure has to put a question mark against almost all permanent magnet motors of that type, especially since Mike Brady experienced exactly the same thing and Australian developers with a successful "Lutec" magnet motor found that they could not replicate it unless they used parts from their original prototype. The V-magnet system of the Hohl Motor in chapter 1 is an exception to this problem.

[Mike Brady's "Perendev" Permanent Magnet Motor](#) (chapter 1)

This design is in exactly the same position as Howard Johnson's Permanent Magnet Motor. It seems that Mike has experienced considerable difficulty in constructing working copies of his prototype. If you want to try to build one, by all means feel free.

[Floyd Sweet's "VTA" Magnetic Generator](#) (chapter 3)

Shown on video, producing more than 500 watts of mains output power for 1.2 milliwatts of input power, this is clearly a device of major importance. Unfortunately, we do not have Floyd's method of producing isolated and easily moved magnetic poles in a block of magnetic material and that is a major obstacle for the would-be replicator. I am not aware of anyone who has successfully replicated Floyd's device.

[Oleg Gritsevitch's Toroidal Generator](#) (chapter 5)

This incredibly successful and powerful device which produced 1.5 megawatts continuously for two years, took major equipment to get it started. It is not known if it can be successfully constructed in a smaller size and the coating between the water in the toroid and the toroid casing may be difficult to achieve.

[Tariel Kapanadze's Electrical Generator](#) (chapter 3)

Unfortunately, Tariel has repeatedly refused to reveal how his designs operate. He has also been involved in several very questionable business deals where the other party felt cheated. It is most unlikely that he will ever reveal the details. Replicating it is not really a beginner's project and an overunity.com forum has been trying to replicate it for a long time now.

[Hans Coler's Devices](#) (chapter 9)

The passive design of Hans Coler can certainly be made to operate if you can persuade it to begin oscillating. The output is quite small but interestingly, it does demonstrate that we are indeed surrounded by energy which can be tapped for practical purposes. This device needs patience in order to get it going.

[The Meyer-Mace Isotopic Generator](#) (chapter 3)

I have never heard of this design being replicated. It calls for a 21 MHz generator which is quite a high frequency for the home constructor. The design itself is certainly simple but getting it to work if it doesn't function initially is not likely to be easy. The Nuclear Magnetic Resonance involved is explained by William McFreey in chapter 3.

[Ed Gray Power Tube](#) (chapter 5)

Ed Gray's power tube is unlikely to be $COP > 1$. The genius behind his achievements was Marvin Cole whose ambition was to be a chef. Marvin built a motor which was certified as $COP = 237$ by Cal-Tech's independent testing, but when he disappeared from the scene, Ed was left at a bit of a loss. Ed only produced patent applications in order to reassure his investors and he never wanted to disclose anything of worth. Mark McKay's detailed information in the Appendix provides extensive background and Mark has now written a book on the subject.

[Roy Meyer's Aerial System](#) (chapter 7)

I know of only one person who tried to replicate this design. The first time he tried it, it worked ok although it was not aimed in the 'right' direction, but he was never able to get it to work again. So it appears that while the design may well work, it is not easy to replicate and get functioning.

[Karl Schappeller's Device](#) (chapter 11)

To be perfectly honest, I have never managed to understand the work of either Karl Schappeller or that of Viktor Schauburger. Not properly understanding the design makes me believe that newcomers to free-energy construction work would have difficulty with this device. That may well be an unfair assessment and if you are able to build and use this design, then please explain it to me so that I can document it properly.

[The "HydroStar" and "HydroGen" devices](#) (chapter 13)

These designs have been around for a long time and to date I have never heard of anyone who has managed to build one and got it to work. In theory, they are supposed to allow a car to run with water as the fuel. On the surface, I can see no way that that could happen unless it operates as a version of the Joe Cell, which it very well may do. If that is the case, then great patience will be needed before the vehicle will operate. I would not recommend anyone to build either of these designs.

[Francois Cornish's Aluminium-feed System](#) (chapter 13)

This system is not economical in the broad sense in that it takes more energy to produce or reform the aluminium than is given out when it is converted to oxide in the process which produces hydrogen for combustion. It can be economical for the user in that the processed aluminium is less expensive than oil products. However, the oxide residue generated by the process limits the effective applications for the process as a whole. It is not a good constructional project.

[The Motionless Electric Generator \("MEG"\)](#) (chapter 13)

This is a device which most people find very difficult if not impossible to get to $COP > 1$ operation. If the frame is made of Metglas nanocrystalline material, then it might be possible. However, the design has been around for a decade and it has not (yet) made it to commercial production, so I would suggest that this is a device which is not a good choice for a constructional project.

Devices which are not really possible

[The ShenHe Wang Permanent Magnet Motor](#) (chapter 1)

While there is a patent for this design, there is not enough information for there to be any reasonable degree of success if you were to try to replicate it. For that reason, it probably should not be considered as being a viable construction project at this time. It may well become available commercially at a later date.

[Thomas Henry Moray's Aerial System](#) (chapter 7)

While this device is, without question, a most impressive device which was demonstrated in public on many occasions, Thomas was intimidated and so never released full constructional details of how his device worked. That lack of specific information prevents this from being a realistic constructional project.

[Steven Mark's Toroidal Power Unit \("TPU"\)](#) (chapter 5)

While this unit has been demonstrated on video, showing impressive operation, I understand that it overheats after 22 minutes of operation. That is not a major problem and could be overcome, but the lack of specific constructional or design information makes this a research project rather than a normal constructional project.

[Paul Baumann's "Thestatika" Generator](#) (chapter 13)

The late Paul Baumann designed and built several self-powered generators which were demonstrated on many occasions. These are still in the possession of a Swiss religious commune who refuse to release the details as they think that "the world is not ready for this information". The lack of the vital design information makes replicating the device a non-starter which is a great pity since it has a substantial mains power output which could ease suffering around the world.

Muammer Yildiz's "Ocean Star" Generator (chapter 13)

While the demonstration of this device looks quite like a hoax, Muammer's credibility jumped massively with the production of his current permanent-magnet-only motor which has been demonstrated publicly. The "Ocean Star" device was supposed to be able to power a house, but the patent information is not nearly clear enough to deduce how to build the device. Perhaps somebody could ask Muammer to explain it in more detail and disclose the key design details in order to allow home-built replications.

Topic: Electrolysis

Question:

I was reading the D9.pdf file you put together on Bob Boyce's electrolyser and PWM3G circuit. The close up picture of the PWM3G circuit shows only 5 LED lights but below under the **Testing the Completed Board** section it talks about 8 LED lights. also on the animated picture (the one with all the components on the board) there are 8 led lights. did bob build another type of board with fewer LED's on it? If so could you explain how to test the different board? Also I was considering buying the board from the Hydrogen Garage website, would you recommend this?

Answer:

The D9 document was created long before the 3G version of the board was produced. The version shown in the document is only there to give an impression of what the board was like at the time. Bob has always been reluctant for any specific details of his circuits to be published which is why the circuit schematic is not shown in the document.

The supplier of your board will tell you how to tune it. I would not expect it to be a different method. Essentially, you start with the frequency variable resistors in their central position and the Mark/Space resistors set to about 10% On time. Then you tune the top frequency of 42.8 kHz to give the best gas output. You then adjust the middle frequency to give the best gas output. Finally, you adjust the lowest frequency channel to give the best gas output. The Hydrogen Garage in the US or Courtierstown Marine in the UK can advise you.

The Hydrogen Garage is run by a very honest and reliable electrolysis enthusiast with many years of practical experience behind him, and there is no reason why you should not buy from there if you want to.

Question:

OK, so if I want to build one of those boosters and I have 14.8 volts in my car how am I going to power 18 plates 5" x 4". That's the only thing that's confusing because there would not be enough voltage

Answer:

I'm not sure where the idea of 18 plates came from. It is likely that your electrics give 13.8 volts rather than 14.8, although that is not critical in any way.

You are aimed at seven cells in a chain so that each cell gets about 2 volts across it. If you put partitions in your box, then with your proposed current you would use just two 5" x 4" plates per cell - a total of 14 plates. If you wanted to provide more plate area, then you would use three plates per cell, making 21 plates.

However, if all your journeys are short and the cell will never get up to its full temperature due to the short time it operates, then you could go for just six cells and with three plates per cell and that would make 18 plates.

If you use separate plates, then you have the difficulty of making good-quality electrical connections between six pairs of plates, and that can be quite difficult to do. I would suggest that you consider the bending method shown at the start of Chapter 10 as that overcomes the need for making any electrical connections inside the cells.

The best plate performance is with two to four square inches per amp of current. As only bending is involved, it would pay off to have a generous plate area, especially if you are using mesh. Mind you, the mesh surface area is not much reduced by the holes as the surface around each hole as it passes through the thickness of the plate is also active. The hole edges are also very helpful in getting the bubbles to break away when the cell is new. Later on, when the cell is conditioned, the bubbles will not stick to the plates at all.

Question:

Is it possible to generate electricity using hydroxy gas?

Answer:

Yes, it is perfectly possible to generate electricity using hydroxy gas:

1. Take a standard electrical generator such as a Honda 6.6 kVA V twin or a Vanguard V twin.
2. Adapt it by filling in the timing key slot and cutting another which lets you set the spark timing to two degrees after TDC.
3. Build any electrolyser capable of producing 5 lpm of hydroxy gas.
4. Feed the generator air, hydroxy and cold water mist from a Venturi tube, pond fogger or miniature carburettor.
5. The generator can run well on that and produce kilowatts of excess electricity over and above the amount needed to power the electrolyser.

This has already been done on at least nine different generators and run 24 x 7 for two and a half years now. However, please be aware that generator engines wear out eventually and will need a rebuild or replacement, so the electricity produced is not "free".

Q: What mmw (efficiency) rating of hydroxy generation is need to achieve this? Also, is it necessary to be using some type of resonance system or will brute force/catalytic electrolysis work?

A: You can use any type of electrolyser you like. Unlike the alternator in a vehicle, a generator is designed to put out a major amount of electrical power on a continuous basis. So, if you take half a kilowatt or more generating the hydroxy, who cares? If the generator is called a 5.5 kW by the manufacturer and you wish to run it at 4.5 kW assuming that the seller is being generous with his rating in order to compete with other brands, then if you use 0.5 kilowatts (12V at 40 amps) for electrolysis you are definitely in business. The two makes of generator quoted, have proven very reliable in long-term use. The addition of very tiny cold water droplets is a key factor in making this work.

Question:

Do you know if the V-twin Vanguard and Honda generator you have mentioned, do not have the waste spark? I would like to buy one, but need to make sure before doing so.

Answer:

The people who have done these conversions say that retarding the spark to 2 degrees after Top Dead Centre was sufficient. Never having worked on internal combustion engines, I can't personally confirm it myself from my own experience.

If you decide to do it and are successful (as I would expect), then I would be happy to produce a document for you which would go out under your name. If you decide to do that, then please take photographs before, during and after your filling in of the timing key slot and the cutting of the new one as that is one item which would benefit from having detailed pictures. Supplier details for the cold water mist device which you pick, be it pond fogger, Venturi tube or miniature carburettor, would be helpful for others following after you.

Question:

Do you have any values for Peter Lowrie's coils, the ones mentioned in the doc are "from a commercial installation with copper sheet wrapped around them" as it is my intention to use a Marine alternator.

Answer:

There are two different techniques for producing hydroxy gas:

1. Pulsed DC signal which can reach 1,200% Faraday.
2. Brute force DC which is usually less than Faraday although with great care, it can reach 212% Faraday.

Peter Lowrie used a marine alternator solely because he wanted three separate 2-volt supplies at 900 amps each. It was because of his very high current that he used an industrial 3-phase power supply choke. Unless you are aimed at currents that high, then you definitely don't need chokes of that massive current capability.

If you are determined to use a similar item, then you need to look at the spares options for professional, commercial equipment. Peter only used a marine alternator for its very high current producing capability and he told me that a second-hand truck alternator would do just as well.

Question:

You said...

"When that gas is added to gasoline droplets in a gasoline engine, it acts on those fuel droplets during the compression stroke, breaking those long chains of hydrogen and carbon atoms into shorter, more active fragments of chains. This produces more active and better combustion of the fuel when it is ignited by the spark, and that extracts more energy from the gasoline, energy which would have been wasted in the catalytic converter and in producing unwanted excess heat in the engine".

This is the first time I have heard that the Hydroxy is doing something BEFORE it is ignited. I thought the Hydroxy ignition was what was breaking down the gasoline into short molecules? Can you explain this more?

Also, can you email me here or privately what you feel are the best Free Energy Devices these days. I think many may be interested in Free Energy Devices to drive their electrolyzers. I'm interested in the devices themselves. Also, is anything near to coming to market?

Answer:

On 14th January, Bob Boyce's post to his Hydroxy forum included the statement: "When either hydroxy gas, or HHO, is compressed in an engine cylinder, it is after it has been diluted with intake air, as well as fuel in non-diesel engines. Not only does the dilution in air raise the auto-ignition pressure, but in non-diesel engines the orthohydrogen has already bound to the long hydrocarbon fuel chains and broken them prior to compression. As this bonding occurs, orthohydrogen decays to parahydrogen. It is the energy from this decay which breaks the hydrocarbon chains into simpler hydrocarbons. These simpler hydrocarbons combust much more efficiently and completely. With diesels, the process is slightly altered, as there is less time for bonding to occur, so improvement occurs much better at lower RPM than at higher RPM".

Gasoline molecules vary from chains of seven carbon atoms surrounded by sixteen hydrogen atoms, to chains of nine carbon surrounded by twenty hydrogen atoms. These chains need to be broken down in order for those hydrogen atoms to combine with oxygen atoms from the air in the cylinder, to produce the heat and expansion which powers the engine. That is why the spark is generally about eight degrees before Top Dead Centre, giving time for this to happen. The more broken up those chains are before the spark, the better.

With regards to free-energy devices, I get asked on a regular basis, what device is best for somebody to try building. The question always comes without the relevant details needed to even make a rough guess at a realistic answer. There is generally no information on country, skills, tools, finance, workspace, time available, main objective, local materials available, environmental space, etc. etc.

Obviously, if someone has converted a pick-up to electric operation and could put a water-fuel generator in the back, the kilowatts of excess electrical power would extend the battery range substantially and would recharge the batteries during a meal break or while away from the vehicle.

This chapter is an attempt to answer your question as to what devices you might choose to attempt to replicate. There is massive opposition to any free-energy device being brought to market. Shenhe Wang intended his permanent magnet motor/generator design to be given freely to all countries in the world. I always felt that he had to be completely unaware of how governments who get billions per year in oil taxes and utility company taxes, would view such a venture, not to mention the oil companies who would see their massive revenue stream being threatened by the introduction of a small device which can output kilowatts of electrical power without using any form of fuel. At this time, it appears that Shenhe's generator is being restricted to China, which hardly comes as a shock.

Chas Campbell in Australia has a viable, commercial machine which also produces significant power without the need for any fuel. He can't find anyone interested in manufacturing it and his local power company just doesn't want to know. However, there are several devices which are nearing being brought to market at this time, and I would expect to see them in use early in 2013.

Question:

I have bought a 7-cell, series-connected electrolyser but the terminals are not marked for Plus and Minus connections. Does it matter which way round it is connected?

Answer:

Any series-connected electrolyser will operate well when connected either way around. However, there is an effect if the unit has already been run. If you are aiming for the top level of efficiency of DC electrolysis, having prepared, cleansed and conditioned the plates with Bob Boyce's methods, then the plates will have been conditioned with the current flowing in one direction. If the direction of current flow is reversed on Meyer type cells the conditioning reverses, the performance drops off and then the conditioning rebuilds, bringing the performance back up again. I am reasonably sure that the same thing happens in a Boyce conditioned electrolyser, so if at all possible, try to identify which way round the unit was originally connected and keep to that direction of current flow.

Question:

In Bob Boyce's electrical diagram, it shows three heavy-duty chokes: one from the rectifier bridge positive, one on the negative and one from the positive line to the circuit board. My question is: "what is the value or specification for these chokes and where can you find them?"

Answer:

There is a document called "D9.pdf" which provides the details of Bob Boyce's resonant electrolyser design. On page 30 of that document, immediately under the circuit diagram it tells you the choke core, the supplier of that core, the wire used to wind the choke and the number of turns to be wound on the core.

Question:

What size hose would be required to run a V-8 on all hydroxy? Does anyone have a flow chart for gas, or know where to find/get one?

Answer:

It is not possible to answer your question directly as we don't know what rate of gas flow you think would be needed or how long the pipe has to be. There is a table of pipe sizes for various gas flow rates on the web site: http://www.engineeringtoolbox.com/natural-gas-pipe-sizing-d_826.html and as 1 cubic foot per hour is about 0.15 litres per minute, if you were feeding the engine 150 lpm, then the table entry would be 1000 cu. ft./hr. and you would be looking at the nominal pipe size of 1.25 inch inner diameter. My guess would be a 1.5 inch pipe as the less restriction to gas flow the better. If you want to get a feel for the capacity of any particular diameter of pipe, then try blowing through it. The results are surprising and a small pipe around a quarter of an inch in diameter (6 mm) is incredibly difficult to blow through in spite of looking like an easy gas-flow path.

The amount of gas needed for your engine is reduced massively if you add cold water mist to the intake air. Nobody can answer the question for you because engines vary so much. Even supposedly identical engines have very different gas requirements, so you really need to experiment with your engine to discover what it actually needs. There is some cold water mist information in Chapter 10.

Q: Thank you for that chart, it's just what I was looking for. Now that I know what size of pipe can carry any particular gas-flow rate, I guess the real question is "how many lpm would it take to run a 318 cubic inch Dodge motor?" I read somewhere that it takes 80 litres per minute per 100 cubic inches of engine capacity. I may have got that backwards. Any thoughts?

A: Unfortunately, there isn't any fixed answer to your question and you definitely can't use a rule of thumb to get a reliable answer. Using cold water fog from a pond fogger reduces the amount of hydroxy gas needed by a large percentage, so try reading Chapter 10 which explains this. You need to understand the operating principles if you are to be successful. Also, you have a much easier task if you start with an engine which is much smaller in size, so I suggest that you begin with an electric generator of about 6 kilowatts as described in Chapter 10 before trying to run a very large engine of 318 cubic inch capacity (5.21 litres), which is about twenty times more difficult.

Question:

I am trying to make different devices in order to improve gas mileage on my car. However, I have some difficulties in understanding the automotive circuits. Could you, please, help me?...

I found in Tad Johnson's experience this: "What I found frustrating is that the cell temperature would change and the system would stop making gas. In order to keep the system making gas you constantly have to keep the cell in resonance, and thus you really need the system to be controlled by a processor, that constantly checks frequency on both legs and then adjust inductance to keep the cell in resonance. This is why Stanley moved to the other patents where the spark plug type of electrolysis chamber was used instead of a large cell."

In this case you gave me a clue in this paragraph: "A John Bedini pulser circuit can be used very effectively with a cell of this type and it adjust automatically to the resonant frequency as the cell is part of the frequency-determining circuit."

First, I didn't find in your book a Bedini pulser circuit so please give me direction where I can find it.

Second, in Stan Meyer's large cell, I understand, we have two kinds of resonance. One resonance is in an LC circuit where the "C" is the cell itself and the coil is the "L". This is electronic resonance. Another resonance is mechanical resonance where the tube pairs vibrate at the same frequency as the electronic circuit (or a harmonic of that frequency). In this case if I make a device to check the current of the cell, this device can adjust the frequency to be identical with the frequency of the tubes, because the current is in direct relation with resonance. If I am wrong, please let me know.

In your book there is a quotation which says: "I plan to market a pre-programmed chip capable of making any hydroxy system work. While I plan to have a profitable venture with the professional pre-programmed architecture, I also believe in the open source do-it-yourself community, which is where I got started. The chips I plan to sell will be a 'plug and play' device. You send me the info on the type of vehicle you are modifying, and the efficiency data of your cell, and I'll be able to send you a chip that will make your ECU work with those conditions. The Do-it-yourself version would be quite time consuming but, would work for less than one quarter of the price." I may be interested in buying the chip if you let me know the price before I order it.

Answer:

Tad Johnson used 1,200 volts and was able to get 3 lpm of hydroxy gas at just 1 milliamp of current (1.2 watts) but he found that he could not scale it up for greater gas output.

Chapter 10 has a circuit which finds and holds a cell on its resonant frequency and that circuit will be available ready-made from Courtierstown Marine in the near future. The Stan Meyer "Water Fuel Cell" has been replicated by Dave Lawton of Wales and the full construction details are in Chapter 10. Further advances have been made by Dr Scott Cramton who is getting 6 lpm on just 12 watts of input energy (plus the waveform from the generator which he is boosting - probably 36 watts overall - 12 volts at 3 amps) and who can reduce the diesel requirement of any diesel engine or generator by 60%. Chapter 10 also shows how to run an electrical generator on water alone.

The ECU piggyback chip details are found in the <http://www.free-energy-info.tuks.nl/D17.pdf> document and it is Les Pearson of the USA (lespearson@hotmail.com) and not myself who is dealing with piggyback chips. I am located in the UK and European vehicles have a completely different computer control system to the ECUs of vehicles in the USA.

Question:

My project is to deliver HHO to a Mazda turbo rotary with 13 lbs boost. I'm not comfortable about injecting HHO into the low-pressure side of the turbo. Even though it's mixed with incoming air, the turbo radial scroll is a wicked device with lots of sharp blades and turbulent flow. The discharge air at full power can reach over 300 degrees Fahrenheit and easily exceed the 13 lbs boost to compensate for losses. This pressurised air charge is sent to a double-pass intercooler before going on to the manifolds. A violent, hot, and long path. If the HHO survives the journey it has definitely reverted to diatomic.

I need to know what to expect if the HHO can leave the bubbler/dryer and move directly to a diaphragm compressor (premixed and diluted with air, if necessary) for direct port injection at 20 psi. What data are available to show auto-ignition at 15 psi? What temperatures, concentrations, method of compression, etc. If I can't up the delivery pressure for direct port injection, I might consider stopping development of my prototype. Please, there must be a safe way to do this???

Answer:

This subject has come up several times on the different forums and the experienced people recommend putting the hydroxy in on the low-pressure side of a turbo-charger. The hydroxy gets heavily diluted by being mixed with the incoming air and so its characteristics change before it reaches the potential trouble spots which you mention. I am not an automotive expert and so can't make any useful comments from my own experience.

One or two people have tried putting it in on the high-pressure side and have found it ok, but it is distinctly possible that their hydroxy gas was low-grade and already laced with hot water vapour, lowering its energy level and potential hazard, so my money is definitely on the low-pressure side.

The self-ignition at 12 to 15 psi information comes from Bob Boyce who is easily the most experienced hydroxy user and investigator on all of the forums. That figure relates to Bob's hydroxy which is the highest possible quality and most people never manage to get anything as high-energy as Bob's gas output. The information

comes from repeated experiments by Bob who just lets the pressure build up and then notes the pressure at which it explodes inside his container which is strong enough to withstand the explosion.

Q: Thank you for your quick reply. I am due to meet with Bob Boyce next week. I hope he will have the time (and patience) to deal with my newbie questions but I intend to drill down on this turbocharger thing. For my project, it's mandatory that I run with a turbo, and mandatory that I can feed the maximum amount of high quality HHO. This engine will be developing 400 hp with 13 lbs boost. I think I'll be defeating my purpose if trying to push maximum amounts of HHO into the low pressure side of the intake. First, it will partially displace the necessary air for combustion. Second, it has a torturous route to travel. Third, it will no longer be monatomic HHO when it finally reaches the engine. There must be a better way.

That's why I was hoping to experiment with a medical diaphragm compressor (same as they use to store hydrogen). If I can blend some outside air with the HHO prior to compression, maybe Bob can tell me what ratio of air/HHO to offset/raise the self-ignition. I'm only looking for 20 psi so maybe the dilution won't be a big deal. Anyway, I'm trying to maintain the purity of the HHO prior to engine combustion.

A: Bob Boyce, who is a very highly experienced hydroxy researcher, states categorically, that you should use the low-pressure side of the turbocharger. I am reasonably certain that there is no need for you to pre-mix the hydroxy and air as that happens adequately during the normal intake process, but Bob can certainly give you much more specific detail on this than I ever could. The pressure for self-ignition is raised enormously when the hydroxy is mixed with air, so it should not be a problem in your case.

The objective is to extract a higher proportion of the energy contained in the normal hydrocarbon fuel, and not to add in energy produced by the combustion of hydroxy gas. That being the case, the amount of hydroxy does not have to be enormous for there to be a very significant gain in engine power and thrust quality. Again, Bob is the man to give you the specifics. Good luck with your project, and I hope your visit to Bob works out well.

Question:

I'm spending my day watching YouTube videos of Bob Boyce. It seems every minute I'm learning more and more. Big problem for me is (-40) cold weather and freezing of the water when not in use. (Canadian winters are brutal). The bubblers can be filled with KOH, no problem there. Same with the main cell if I use KOH. But the biggest problem is the water reservoir and supply lines. I had thought of 50/50 blend of methyl hydrate/water (windshield washer fluid) but, according to one of Bob's videos, the carbon will bond with the nickel in the stainless steel plates and eventually stop gas production (sigh). If I had a consistent and reliable electrical power source, I could just plug in a heater of some fashion, but I won't always have that luxury. Any thought on the subject??

Answer:

Please do NOT put KOH in your bubblers as a major function of the bubblers is to wash all traces of KOH out of the gas before it reaches your engine as traces of KOH are not good for your engine. You can use alcohol or paraffin ("kerosene" in the US) which many Canadians have found satisfactory in bubblers as the fumes are not harmful to your engine in any way. If you are boosting, then the water usage will be so low that you can manually top up with warm water from time to time.

Question:

I have watched the interview of Bob Boyce with Chris Patton countless times, even now, looking for signs of 'bullshit'. I have a good intuition which I trust and listening to Bob I can't help but like the guy and still believe every word he says. I'm a plumber and have no previous experience with hydrogen. I've built a 101 plate electrolyzer following your plans and I'm getting 4 lpm when using 190 volts DC and about 4 amps of current.

I've wound my toroid and just run out of money for a scope to try to get the resonance. I've noticed that no one seems to have ever replicated what is described on your website and that Bob is copping it on the forums. I believe him still, but I was wondering in your opinion why is it that no one has managed to get 50 lpm or anything mind blowing? Where could the problem be? I'll tell you one thing though, I'm gonna keep at it as soon as I can afford a scope.

Answer:

Resonance is very important in any COP>1 system, which is what Bob Boyce's hydroxy system is. I'm not sure about your need for an oscilloscope, but don't let me discourage you from getting one. If you have not seen them, the series of YouTube video clips on resonance <http://www.youtube.com/user/gotoluc#p/u/15/L0AZkovLTT8> should be both interesting and helpful.

Dave Lawton has designed and tested a circuit which finds and locks on to the resonant frequency of his style of cell. That circuit is available as a pcb, a kit, or a ready-made unit from Courtierstown Marine in Aberdeen.

However, Bob Boyce's design calls for three drive channels instead of just one. Bob has designed, built and tested what he calls his "Hex Controller" which is probably a PIC chip programmed device. He has kept it secret while he applies for a patent on it, but it should become commercially available shortly. I understand that like Dave's design, it locates and locks on to the resonant frequency of the cell.

When not tuned to resonance, the pulsing system should give about three times the gas output of the DC cell performance. When tuned to resonance, the increase should be five or six times.

As you are probably aware, the electrolyser needs to have the plates cleansed and conditioned as described in the D9.pdf document on Bob's unit. Then the cell needs to be "run-in" on DC until it gives around twice the Faraday output. After that, the unit is filled with 28% by weight KOH electrolyte and fed the pulsing signal.

Faraday defined electrolysis as being 2.34 watts per litre per hour of gas output. That is $2.34 \times 60 = 140.4$ watts for 1 lpm of hydroxy. At this time, you are feeding in 4 amps at 190 volts which is 760 watts. For that 760 watts Faraday would expect 5.41 lpm, which means that your unit is running at 74% Faraday, or about one third of the expected output from Bob's design before it is ready to go to pulsing operation.

Admittedly, the 190 volts is fractionally low for 100 cells, but it is close enough not to be any problem. So, at this point in time, your cell needs mechanical attention in order to get up to the 11 lpm or so that can be achieved on DC alone. When it reaches that level of performance on a 10% NaOH solution, it should then achieve 33 lpm or more with untuned pulsing. But the first step is to get the cell to it's necessary DC performance level, which, unfortunately, probably will need the plates to be prepared to a higher degree.

Unfortunately, there is a difficulty with Bob's design and that is that the plates need to be positioned and sealed to a degree well beyond the capabilities of the average person to construct. If you bought your case from Ed Holdgate, then there will be no problem, but a home-made case can't generally be constructed to the necessary 1/3000 inch accuracy by the average person, as that is a skilled job for an expert machinist who needs to know the exact, actual electrode plate thickness before he starts making your box.

The need for that extreme accuracy is because the resonant operation sets up a magnetic waveform inside the plate array and that won't happen unless the plates are positioned VERY accurately. The gas bubbles form in the electrolyte between the plates rather than on the plates and when that happens it looks like the electrolyte is boiling although it is actually quite cool. I'm sorry that my reply has to sound so negative especially since you will already have put in a large amount of effort on your project. Good luck with your upgrades

Question:

You must be busy, but I'd appreciate any feedback about this link:

http://www.pureenergysystems.com/news/2005/03/17/6900069_Acetone/ Would you say engines in good condition get improvement, or the opposite? In your opinion, could I damage a diesel tractor engine, or car gasoline engine by trying small amounts of acetone added?

Answer:

There was a lot of discussion about acetone some years ago. Some people got around 20% mpg improvement while others got no improvement at all. It appears to depend on the engine and the condition that the engine is in when the test is run. You need to understand that I am not an automotive expert and so my opinion does not count for much. I would expect it to be the older and poor-condition engines which would benefit most from acetone - which, incidentally, is a fairly dangerous substance for humans and needs to be handled with considerable care as it can be absorbed through the skin and by inhalation and it can cause kidney damage.

I don't think that you will damage any engine by adding some to the fuel. Having said that, you can get up to 60% fuel reduction on a diesel engine by adding hydroxy gas in sufficient quantity and petrol engines respond even better than diesels. The GEET device allows a major reduction in fuel use and is very popular in France where many tractors use it. The <http://www.panacea-bocaf.org> web site has a good deal of information on it and are experimenting with it at this time. There are also two GEET enthusiast forums.

Question:

I have a Ford "Transit" diesel 70 hp manufactured in 1995. Is it possible to add hydrogen in order to let it run with less fuel consumption and be more environmentally friendly?

Answer:

The fuel consumption of a diesel engine can be reduced by anything up to 60% by adding hydroxy gas to the incoming air. As far as I am aware, no modification to the engine is needed. The improvement in fuel consumption is proportional to the amount of hydroxy gas added. I hope that this helps and good luck with your project.

Question:

Hello, we need your help. Based on your 6-cell model of Chapter 10, we have built such a generator, which is as follows:

- Stainless steel type 304 (do not get the 316), calibre 0.08.
- Badges 4 "1 / 4 X 2", 4 plates per cell, total 24 plates (206.4 in²).

NaOH was used as electrolyte, with a concentration of 20% (as described in chapter 10), we just apply 13.5v a current consumption of 1.5A. We use a higher concentration of electrolyte at 30%, 40% and gave us the same result with a current consumption always similar to 1.5A. We need to know because consumption is so low that, according to calculations based on Chapter 10, current consumption with 12V, it should be up to 40A. Or have we miscalculated? See attached image.

Answer:

You have invented your own plate arrangement which needs 6 volts per cell because you have 3 (very inefficient) voltage gaps inside each cell. At this time, you are applying only 0.7 volts between each pair of plates and that is why the current does not change much with stronger electrolyte. You need to change the plate arrangement to what is shown in this drawing. Good luck with your project.

**Question:**

In the WaterFuel1978 Yahoo forum, the contributor "s1r9a9m9" says that he runs his large capacity car which has 8-cylinders, using just water and an inverter. Do you know of anyone who has replicated this?

Answer:

I am reasonably sure that Nathren Armour is a professional con artist, paid to mislead people investigating how to run an engine on water. "s1r9a9m9" (Nathren Armour of the USA) came on the scene about four years ago. I didn't believe him at all, so I asked him some questions by direct e-mail. I was very surprised when his answers were quite convincing. This was in the old "egaspower" forum. So I wrote a document drawing together all that he had said about the design and adding in each relevant post by people in the egaspower forum who tried to understand and build his design.

After two years of intensive experimentation by several competent people, there was not the slightest success by anyone. Because of this, I withdrew the document "D13.pdf" (although there are probably copies still floating around). I no longer believe that anything Nathren says now, or said back then, is true. In the early days, he posed as an uneducated country car mechanic, who for some unknown reason, was asked by NASA to make some component for a mission to Mars. Why NASA should rely on a country car mechanic is not at all clear. At that time, he told me in a direct e-mail, that he had converted his own personal car, and the engine out of a truck which he used to power an electrical generator, and the cars (plural) of his friends.

His car has 8 cylinders, the truck at least 4 (though probably more), at least two friends with four cylinder cars, makes a minimum of 20 relays needed, plus one which he took apart to see how it was made, so say 21 although 27 would be a more likely number. When writing at that time, his posts were written in broken, uneducated English with a space before the full-stop at the end of each of his sentences.

Now, his posts are in much better English, the gap before the full-stop has gone and the relay count which he states, contradicts what he told me by a really major factor. He no longer allows for the relays used for his friend's cars, or the one which he supposedly took apart. Any time he was asked for specific information, he always made unconvincing excuses and supplied no worthwhile data.

He has posted videos of the Steorn device, showing bench test equipment of a type which no country car mechanic would ever own or understand. His videos have sound but he does not say a single word, which is

most unusual for an English speaker, and in this case is highly suspicious.

My opinion is that his information is wholly fake. It is distinctly possible that this con is now being carried on by a second fake "Nathren Armour". I have never heard of anyone managing to replicate any part of his supposed invention, and I doubt that anyone will ever manage it, although I would be delighted to be proved wrong.

It is perfectly possible to run an engine of any size on what appears to be water alone (the engine actually runs on stored energy drawn directly from the local environment, coming mainly from our Sun). I know of several "petrol-powered" electrical generators which have been converted to run on water in spite of the fact that the efficiency of their tiny internal combustion engines can be as low as 10%. Some of those generators have been running continuously for more than two years now.

Running a large engine on water alone is a much more difficult task but it can be achieved by the energising and injection systems of Stanley Meyer. Sorting out a system of that type has been quite difficult as Stan developed many different types and styles of adaption and it was not immediately clear to me, which of his descriptions apply to which of his systems. Additional information from the contributor whose ID is "H2Opower", has been most helpful, and Stan's design is now much more understandable, which means that replications are now a distinct possibility.

Question:

My daughter came to visit from California. She got 27 miles per (US) gallon average on the trip up here with her Buick Regal. For her return trip with a full car load of her stuff I installed an improved (single water bath) electrolyser, current control with a BASIC Pulse-Width Modulator, and I made her a MAP sensor enhancer override. She followed the same route back to California and averaged just under 40 miles per gallon (a 45% increase). No other changes were made. The electrolyser has eight 2.5" x 5" stainless steel plates with 1/8" spacing in a Mason jar. The plates were all cross-hatched with sanding score marks and all skin oils were removed with trichlorethylene (Automotive Brake Parts Cleaner). I used the method Boyce recommended of polarizing the plates with a wire wrapped around the body of the plates and sparking across a 12 volt DC source. I set the Pulse-Width Modulator to supply 18 amps steady once warmed up. Previous to this project the best I had achieved is a 23% increase. Your book helped me to tweak a few things and waah-laaaah 39+ mpg.

I do have one problem which I've been trying to figure out. I am building a Don Smith type device. The unit he showed is rated at 8,000 volts at 20 amps (160 KW). I used a 10 foot section of #12 solid copper wire for the L2 coil wound around a 2" pvc pipe. I then released the hold on the wire allowing it to expand to approx 3" diameter coils. Then I cut four ABS plastic strips and hot glued them into the interior of the coil spaced evenly. The coils are spaced at 3/8" space per turn. I then used insulated #12 multi-stranded (maybe 50 strands) wire 2.5 feet long for the L1 coil wrapped around a 1.5" PVC pipe which made about 5 and 1/8 turns. the excess wire was run through holes into the centre of the pipe and carried through to near the lower end to exit the pipe and was then led to the terminal strip for the neon generator.

The neon generator throws a 2" spark until it is hooked to the coil. Once the L1 coil is hooked up I can't get the slightest spark! The spark gap will not arc even a 64th of an inch. I've tried rectifying the output of the neon transformer and tried direct hook-up. It seems odd to expect that a spark could be drawn with the L1 coil direct shorted across the transformer output. My understanding is that the spark gap is required to maintain the frequency as a trigger when DC is used, but that it is not absolutely necessary with AC. Is this your understanding? I know from Tesla's drawings that he commonly used them, but often it was after a capacitor.

When I was looking at the photo clip of the device I didn't see any diodes. Could they be in the black insulating tubing on the terminal strip? Do you know why he converts to DC before he goes into the coil, when he again rectifies with a bridge after the L1 / L2 coil assembly? Could he just as well be using AC until he completes the zero-point energy collection process like Tesla often did or are you positive he has diodes in there at the neon transformer?

One last thing... Do you know how I can read the frequency of the neon's High Voltage High Frequency output with an oscilloscope? I tried to contact the sellers of the devices and they have no idea what the frequency of the output is. They just read what the data plate says on input frequency. I am now trying to get the info from the manufacturer, so far unsuccessfully.

Answer:

May I suggest that you hold off on your assessment of the improvement in mpg got by your daughter. Some ECUs are programmed to adapt to changes such as the addition of hydrogen, and after a few days or weeks, revert to pumping in excess gasoline. Let's see what the effect is after some time has passed. Certainly, the improvement achieved so far is a good indication of what is definitely possible in spite of the opposition from the ECU.

I'm afraid that the suggestion on wrapping wire around the plates and pulsing it, came from me rather than Bob Boyce, who I understand thought that it was a ridiculous idea until one electrolyser builder told him that he had got a substantial percentage gas improvement by doing that. In theory, if the steel is perfect, then it would have no effect, but if, as can happen, the steel supplied is not perfect, then it could help, especially in the early stages of electrolysis.

The devices described by Don Smith are probably the most difficult you could try to replicate (with the possible exception of the Joe Cell). Each of Don's devices need to be tuned to resonance which is difficult to do unless you have a lot of patience, equipment and know-how. Your construction method sounds great and your choice of materials, very good - most people ignore what they are told and decide to do something else and then say that "it doesn't work", while in reality, they should be saying "I couldn't get my altered design to work".

In my opinion, the spark will not occur unless you have a capacitor across the L1 coil, forming an L-C combination which has high impedance at the frequency produced by the neon driver circuit. On it's own, I would expect the L1 coil to load the neon supply too heavily to get any serious voltage across it. As an L-C pair, the impedance at one particular frequency will be very much higher (which is how an AM crystal set radio receiver tunes in a particular station). The spark will only occur at resonance as the voltage will be pulled down too low at all other frequencies.

The diodes are hard to see in the video. They are long and black and don't show up well against the dark background. There are actually four of them on the output side and as you correctly remark, Don describes them as a bridge. They are very long because of their high voltage rating, perhaps ten times as long as they are wide.

I think that the neon driver which Don had, gives two separate high voltage outputs and Don combines them on the input side of L1 with two diodes to stop them interacting with each other. Your neon driver circuit is liable to be very different to Don's.

The frequency and shape of the neon driver output pulses can be read with an oscilloscope. You set the horizontal time adjustment so that you have two successive pulses widely spaced on the screen, and then the horizontal timing setting combined with the number of squares on the screen between the start of each pulse shows you how far apart in time the pulses are. If the time between them is 0.033 milliseconds, then the number in one second (which is the frequency) will be the number of 0.033 milliseconds which fit into one second (of 1000 milliseconds), i.e. $1000 / 0.033 = 30,000$ pulses per second or 30 kHz.

Topic: Magnetic Motors

Question:

If a Flynn Magnet Motor has an even number of magnets and coils on the Stator, how does the motor self start when power is applied, if at all?

Would the assumption be correct that the position of the two magnets on the rotor would be slightly off the exact point of registration of their opposing coils in the direction of rotation, say by 1 or 2 degrees or less perhaps as power is applied to them? The next obvious question would be, how long does the energising pulse have to be? I realise it has to be long enough for the face of the rotating magnet to pass over the Stator magnet. After how many degrees will the rotating magnet be caught in the attraction flux of the next magnet? This period of the coil being energised must obviously be as short and effective as possible, since this will determine the input power.

You state in the literature that the two opposing coils, 180 degrees apart are driven in series. What's the reason for series instead of parallel? If current consumption is the problem, then an adjustment in coil design could easily make a parallel connection draw the same current as a series connection, no?

I know this is not a reasonable question but one I wish to ask anyway. If a motor with the magnets I propose to use, works and works well, using a single platter with the specifications as they are, what could one expect in the way of output power, and what would the total input power be? IF and that is a big IF, this design could attain, even 6000 rpm, it could generate considerable power. If speeds of 20 000 rpm as claimed by Flynn are possible, then I guess even a small motor like this one, could in fact yield a heck of a lot of power !!

Answer:

Self-starting requires a different number of stator magnets or coils to the number of rotor magnets. If the numbers are the same and the stator has separate magnets rather than being one large ring magnet, then the rotor will stop in a position with exact registration of the magnets. So if the build does not allow the user to give it a starting twist, then an odd number of magnets are necessary.

I would suggest that you use an electronic circuit to control the length of the pulse but if that is not convenient, then I would suggest a twin-rotor optical method of adjusting the pulse length as shown for the timing of the Robert Adams motor in Chapter 2. By adjusting to position of the two timing rotor slots relative to each other it allows you to control the unmasked slot length in the timing disc and so adjust the pulse length passed to the optical sensor.

Connecting coils in series or in parallel is just a choice governed by the windings and the user's choice of current, as you point out. The point being made in the text was that being exactly opposite each other, the pulses occur at exactly the same time. However, as you point out, that arrangement would have starting problems.

The torque provided by a single rotor depends directly on the radius of the rotor from the bearing out to the centre of the magnets. Another factor is the pull provided by the permanent magnets. The final factor (ignoring the bearing friction and wind resistance) is the speed of the rotor as the number of drive pulses experienced by the rotor depends directly on the rotational speed. I could see the power output of such a motor as being substantial, even with just one rotor, and by adding additional rotors on a single shaft, the power level should be almost unlimited and I can see no reason why a standard electrical generator could not be driven by such a magnet motor. Remember that only one coil is powered at any one time.

Question:

Here is a question which I hope you can answer. I really have no idea why the coils in the Flynn Magnet Motor drawing have such a large area inside the windings. Obviously the shape of the coil follows the shape of the magnet, but why is the centre cavity so large? If the magnets are circular would there still be a large centre hole? I have noticed this in coils designed for wind generators as well. Your explanation would be appreciated.

Answer:

When a current is passed through a coil of wire the strongest part of the magnetic field which is generated is inside the coil windings. The gap inside the coil windings is the most electronically shielded area when the coil is activated and that is why the gaps inside the coils cover the majority of the stator area. This would be the same if the stator was non-magnetic and had circular magnets mounted on it. In that instance, the gap inside the coil would be the same size and shape as the stator magnet and might well surround it.

Question:

I am interested in experimenting with the Phi transformer. I have been reading your free-energy e-Book for quite some time now. You mention tests with a COP of 8.5, namely, 140 watts input and 1.2 kilowatt output. Would you assist by pointing me in the right direction in examining studies/literature on the Phi transformer.

Answer:

I'm afraid that I am just passing on the research information which I have come across, and I have not built and tested everything mentioned in the eBook as that would take a great deal of money and probably several lifetimes.

In the case of the Phi transformer, I only came across it twice. Once on a German website where there was a very nice photograph of an exceptionally well-built prototype and once on JL Naudin's website. Unfortunately, I lost track of the German site and did not take a copy of that nice photograph. I think that the performance figures came from that site. I tried e-mailing JL Naudin about the variation shown by him but he never replied, which I gather is not unusual for him.

I am not aware of anywhere else that carries information on the Phi transformer. Two people e-mailed me about their attempts to replicate it using very rough bent steel strips and spinning the rotor with a power drill. Their initial tests appeared to confirm that there was either very little, or no Lenz Law effect. They soon dropped me out of the loop and went on developing while communicating directly with each other. I don't recall ever hearing their final results but have the impression that they did not do very well. However, my impression of the quality of their construction and testing was that it was not great, and with free-energy devices, a high quality of construction can make a major difference.

Having said that, I would suggest that you pick on some other device with which to experiment and I would like to remind you that the eBook is upgraded about seventy times per year on average, so downloading another copy is probably not a bad idea.

One thing you might care to consider is adapting a generator to run on water alone as the excess output is in the kilowatts range and not much construction work is needed. Alternatively, if internal combustion does not appeal, then perhaps the RotoVerter which can give a 90% saving in the running costs of electrical equipment.

Hope this helps, and good luck with whatever project you pick,

Question:

I've got this idea for a motor and want your feedback. Say you have a wheel, and around the edge you place magnets having the same poles pointed outward. Maybe 30 magnets and all have their north poles facing outward on this wheel. One magnet is then brought, south end first, at right angles to the magnetic field of one of the magnets. The idea is that this will push the magnet in one direction and force the wheel to move, and because all of the magnets have the same pole exposed, this process of continually interacting magnetic fields should keep on for a while. Very possibly a crackpot idea. I'm getting 40 magnets shortly, each with a pull force of 11 pounds, so I hope they're strong enough to do something.

Answer:

It is very difficult indeed to get a permanent-magnet-only motor going and the setup which you appear to suggest is one which is commonly tried by almost everyone. It generally doesn't work because while there is a repulsion on one magnet which drives the wheel around, as soon as the next magnet on the rotor approaches, it encounters a backward push of exactly the same size and that causes the rotor to oscillate and then come to a stop with the magnets at their shortest distance apart. Using electric shielding to block the unwanted retarding action, as in the Adams motor or the Flynn motor, makes a major difference and can produce great results and high rotational speeds. Good luck with your experimenting.

Question:

Regarding the Orbo details in Chapter 1: What Sean at Steorn is saying is that the permeability of the ferrite core decreases as the rotor magnet approaches (I have verified that this assertion is true). When the permeability is at its lowest point, the coil is pulsed with a very small current so that complete saturation occurs. The ensuing small magnetic field then allows the magnet to skate past the ferrite core. Once the magnet no longer influences the core, a large change of inductance occurs in the core, and as Sean states, it leads to an "energy gain". At this point, the flyback voltage can be captured, and indeed, it is greater than the energy it took to energise the coil. The higher the RPM, the more energy can be captured. There are numerous factors involved in all of this, all of which are quite critical in achieving maximum performance -- coil positions, core permeability, speed, etc.

Answer:

Thank you for the detail on the Orbo design. I find it quite hard to get excited about it due to the earlier Adams and Flynn motor designs. I am more than happy that the people in Dublin are genuine as that was my strong impression when I met them on the first day of the failed London demos.

We are only scratching the surface here. I have had person-to-person information on the Adams motor, information which I think has never been made public. Robert Adams was not willing to share his more advanced developments and died before he decided to share his findings. I am informed that he had got a 200 mm diameter rotor motor/generator up to megawatt level output, which is pretty spectacular. I wonder if we will ever replicate that performance.

I understand that Chas Campbell in Australia reached COP=10 before moving on to a more advanced design which he says has unlimited energy output. He says:

"How 2 Fix

To create a power source by using Gravity you must have a constant source of momentum and it doesn't have to be perpetual motion, My system uses an electric motor to generate centrifugal force this is achieved with flywheels. A balanced flywheel attached to an electric motor will actually reduce the power consumption of the electric motor while generating Torque, and you use that extra power to drive another flywheel and so on. Remember, to produce electricity you only have to spin a alternator at its designed speed once that speed is reached you use the torque (hp) to keep it spinning - sounds too easy doesn't it? I can spin a flywheel which weighs 80 kg, at 1,000 rpm and the power consumption of the 750 watt motor is less than it takes to spin the motor when it is attached to nothing.

As a matter of interest, the flywheel has a diameter of 600 mm. Imagine a steel wheel weighing 80 Kg travelling at 113 kilometres per hour. So the next time your electricity bill arrives, ask yourself "why does it cost so much when it can be produced by Free wind, Free sun, Free tides, Free water and Free Gravity which can be produced on site?" No more power lines or high insurance cover needed on your solar panels or wind towers.

Gravity is available everywhere even to the 2+ billion people who live without electricity. I am not smart enough to write a book or design a computer game so I decided to invent something that would make me rich it's been a lot of fun and very frustrating as everybody keeps saying "it can't be done". I am now 73, live in a unit, have a foreign landlord and have spent all my money on my invention. It's time that I told the world how to build the "Safe, Affordable, Helpful, & Clean" generator.

Sir/Madam if you, your company, or your Government would like to be associated with something that will make the world a better, safer place please contact me. I've had a film made that I'm sure you will find very interesting.

If you send your POSTAL ADDRESS with a small amount to cover my costs to my POSTAL ADDRESS, then a copy of the film in DVD mode will be posted to you.

Sincerely,
Chas Campbell
PO BOX 137, Sunnybank, Queensland, Australia 4109."

It looks like Chas has hit the same brick wall of "zero funds" that most other inventors have. He also seems to have been bitten by the "hey, this design is worth a lot of money, so I could get rich here if I play my cards right" bug. If he manages to make big money, then he will be the first inventor to ever do it.

Question:

How can I block the magnetism between two strong magnets for my new magnet motor design? I am using five layers of mu-metal at the moment but I need a complete magnetic block.

Answer:

Your question suggests that you do not fully understand the nature of magnetism, which is not too surprising as it is not really well taught anywhere at the present time.

If you place two circular steel flanges on a plastic shaft, wind a coil on the plastic shaft and power the coil. the resulting magnetic field is strongest between the outer edges of the flanges and weakest at the coil of wire. Unexpected, but true. The reason is that magnetic "lines of force" (for want of a better term) spread out along the paths of least resistance and the flow divides up in direct proportion to the resistance of the paths. Steel has 1000 times the magnetic conductivity when compared to air, so for every 1 unit flowing through the air, 1000 units will

flow through the steel if it provides an alternative path. As the flange diameter increases, so does the area of steel in the flange and hence the magnetic conductivity. The result is that the strongest magnetic field between the flanges is at the outer edge as can be seen from the attached diagram. There IS additional magnetic flow (not shown on the diagram) through the air outside the flanges, but it is very small compared to the flow directly between the flanges.

The bottom line is that it is not possible to **block** magnetic flow with a shield (and mu-metal is one of the very best materials for attempting that). The most you can do is to provide a more attractive flow path for the "lines" of magnetic force, and so persuade them to divert to another direction - they never just stop at a barrier.

So, for your problem, I would suggest just two ways of dealing with it:

1. Use an identical magnet as the "shield" but reversed so that the field oppose each other. That will work, but if your design requires the shield to be moved into position, then there will be a very marked overhead of the force needed to move the magnet against the existing magnetic fields.
2. You oppose the magnetic flow with a magnetic field from a coil, the field only being present when the coil is being powered. That is very effective and the motor power is very much greater than the mechanical power which could be generated from that same electric current. That arrangement is called a Flynn Motor and it works very well indeed.

One other option which does not match your query, is to physically move one of the two magnets relative to the other as is done in the Steven Kundel magnet motor.

Good luck with your project,

Topic: Don Smith's Devices

Question:

I am a bit confused though by the frequency conversions necessary to find the proper length of coil for an L1 coil. On page 338 of PJLBook.pdf it says...

Point 1, section d "If using one quarter wavelength, then divide 247 by the frequency in MHz."

My frequency reads 35.4 KHz or 35400 Hz. That calculates out to .035400 MHz. If I divide 247 by .035400 I get 6,977.40112994 feet. In reading the examples given in Dons pictures and text no reference is given to use of anywhere near that length of wire. In fact the reference to length is in the ten foot range. Am I way off base here or what? Do you come up with the same figures? I have to be missing something, can you help me see it?

Answer:

You are not the first person to ask me that question. It needs to be understood that you are quoting Don Smith and not myself. You should also understand that Don Smith does not reveal everything about any of his designs and I, personally, do not by any means understand all that he says. The Don Smith devices are some of the most difficult to understand and replicate. Don uses various techniques with his different designs although most of those techniques appear to have a common background strategy for energy extraction from what he describes as "the ambient background" and others call "the local environment".

Don goes into the overall principle for estimating the resonant frequency of a coil, where a factor of 247 comes into play. However, a coil and capacitor combination resonate at a different frequency set by their combined characteristics. This is clearly seen in a "crystal set" radio receiver. These very simple receivers can be tuned to a radio station by adjusting the number of turns on a coil. The coil is generally built like a rheostat with a slider connecting to each coil wind in turn.

The tuning relies on the fact that a coil of any particular characteristics such as length, diameter, core material, turn spacing, etc., has one frequency at which it has a very high resistance to AC current flow through it. While we don't tend to think of it as such, a radio signal coming down an aerial wire heading for an earth connection, is actually an AC signal causing an AC current in the aerial and earth connections (and consequently, the coil connected between them). If there happens to be a radio signal which is at that exact frequency, then it finds it very hard to get through the coil and tries to find an easier way past the blockage. The radio builder provides that easier path by connecting a germanium diode and a pair of headphones across the coil. Only that one radio signal takes a detour through the headphones and so the listener only hears one radio station out of the many coming down his aerial.

An alternative construction is where the set is tuned by adjusting the setting of a variable capacitor connected across the coil which has a fixed number of turns. This adjustment causes the coil/capacitor combination resonate at different frequencies, the frequencies of interest are those used by different radio transmitters. The average person thinks of this as "tuning the radio in" to different radio stations, but the reality is that the user is altering the resonant frequency of a coil/capacitor pair. The higher the required frequency, the smaller the capacitor needed.

If a coil has its turns spaced out like the Barker & Williamson coils which Don uses, the coil's inherent self-capacitance is increased dramatically. Dealing with coils energised at high frequencies is a fairly tricky area as there is stray capacitance through the air between components on a board, and so, the physical layout of the

circuit becomes a factor in the design and in some instances, placing your hand near the tuning components can alter the stray capacitance of the tuning system.

Don admits freely that he does not reveal all of the details about any of his designs, but he does share enough for enthusiasts to have a reasonable chance of working out the missing details for themselves. To help with this, he explains a couple of his easiest designs in fair detail. The neon tube driver design is one of these. Here, the frequency of the commercial driver circuit is imposed on the small "L1" primary coil winding. If it is not the natural resonant frequency of the coil, then circuit forces the frequency on the coil by pulsing it at that frequency.

However, one thing which Don does not mention is the fact that the current which will flow through that "L1" coil depends on the applied voltage (which is very high and might be 6,000 volts) and on the coil's impedance at that frequency. The practical details of this radio-frequency work is something about which I am almost 100% ignorant, so you would need to read up on the subject or consult an experienced radio-frequency expert.

In the design which Don shows most frequently, he indicates that the performance of the first part of the circuit is governed by the resonant match between the L1 and L2 windings of the Tesla Coil which he uses to step up the voltage to a high level. To make these two coils resonate in step with each other, the L1 coil needs to be made from wire which is exactly one quarter of the length of the wire in the L2 coil. If the coils were the same diameter, that would give a 1:4 step up in voltage, but as the L1 coil has a larger diameter, the wire length makes fewer turns than one quarter of the number of turns in the L2 coil. Consequently, the step-up ratio is more than 1:4 and more than four times the voltage is generated in the L2 coil.

Don implies that if the coil winding is not absolutely exact, you might need a very small capacitor across the L2 coil in order to make the two coils resonate at the same frequency. If this were the only requirement then you would expect to see one capacitor across the "L2" coil to make the matching perfect. However, you will notice that Don uses a capacitor across **both** of the coils. So, why does he need two? This may be my ignorance showing here, but I would suggest that the capacitor across the "L1" coil has nothing directly to do with the "L2" coil at all but is there to tune the "L1" coil exactly to the output frequency of the neon-tube driver circuit, presenting it with a high impedance at the working frequency and so it will draw very little current from the driver circuit.

The frequency in L2 will always be the same as that in L1 which is driving it, but the energy performance is massively better if the L2 coil is operating at its own natural resonant frequency. This may well be achieved by the wire length ratio between L1 and L2 but as the L1 natural frequency has been manipulated slightly by putting a small capacitor across it, I suggest that the capacitor across the L2 coil is to match the capacitor-induced shift in resonance of L1.

In versions of this design, Don converts the AC coming out of L2 to DC with a high-voltage four-diode rectifier bridge and then feeds the power into a large high-voltage capacitor before stepping the voltage down and the current up, with an "isolation" output transformer.

I have seen it said by several different people that a capacitor used like this causes a change in the nature of the incoming energy, making it much more like conventional electricity.

It seems highly likely that what Don says has a typing error and the "MHz" should read "kHz" and the wire length at your 35.4 kHz would then be 6.9774 feet (not including the straight connecting wires) or 6 feet, 11 inches, and 23 thirty-seconds or 2127 mm. Wound on a 3" former with wire of 0.25" diameter, that would be about 8.22 turns which does not seem unrealistic.

However, bottom line, you have to consider me to be a source of unreliable information here as you are asking me to interpret what Don means and there are probably not many people who can do that and I am definitely not one of them and so have to resort to guesswork here.

With regards to the Ecklin-Brown style motor-driven rotor device, I would suggest that although he does not show it or mention it, that Don tunes the power pick-up coils to the resonant frequency of the pulsing produced by the rotor arms passing by the magnet pairs. Remember that the title of Don's document is "Resonant" Energy Methods and he shows the Ecklin-Brown style device in that document.

Question:

Just to let you know I was at first impressed with Don Smith's research. Having checked other comments about him I now have my doubts. The question is: why did he not commercialise his Tesla system which is described in sufficient detail in your eBook? One of the sites I found did not have good things to say about him. Who does one believe. I sent him an e-mail recently and it just bounced back. It seems that Don has gone quiet.

Answer:

Don Smith is very elderly at this point in time and he has suffered several severe strokes. It is almost certain that he is in no fit state to respond to e-mails. There is a web site set up by his son who gives every appearance of not understanding anything much about his dad's technology.

Don methods are some of the most difficult to replicate as he freely admits that he withholds some vital information because he exploits his designs financially and so Non Disclosure Agreements get in the way. In his various video lectures he remarks that it is not in his financial interests to disclose all of the details but he says that he discloses enough to allow an experienced developer deduce the missing parts and fill in the gaps for himself.

Probably a key point is having the "L1" / capacitor combination reflect a high impedance at the frequency of the driving circuit (probably a neon tube driver). With a high impedance, there is little current draw. Another feature is the need to feed the energy into a capacitor before attempting to use it for "useful work" as the nature of the energy changes in the capacitor and aligns it to our everyday power supplies. The radio frequency experts have a head start in understanding Don's designs as they are nearly all based on high frequency and, for example, RF experts know that metal can be used to insulate between two wires if the spacers are the correct length for the frequency used.

Although Don does not say it, it is probable that his Ecklin-Brown style device has the output coils tuned to the frequency produced by the spinning rotor arms. Also, it is likely that he is using wire with a very large number of fine strands inside it and that seems to have quite an effect on the output.

Question:

I took off from the internet PJK book. I am interested in the device by Don Smith. Unfortunately, since my English is bad, and his logic is a bit different than my Croatian language, I have problems with understanding. The problem is on page 223, chapter 3-37. So I do not understand why I have to divide some numbers with frequency in order to get the length of the wire. For example, if I want to get the wire length in meters for one-quarter the length of the coil, why do I have to divide the number of 75.29 with the desired frequency. What does that number - 75.29? Also I am interested in one quarter wavelength? What do you mean by the term wavelength? Also, do you think that the term quarter means the length of the wire or it means the length of the coil? I counted the number of turns in the coil of Don and concluded that the coil L1 is a $1/4$ of $1/2$ of the coil L2. Can you help me, please, to understand it.

Answer:

Your question is not easy to answer, but I will try to answer it.

If you hit a church bell with a hammer, the bell will vibrate and produce a musical note which depends on the size of the bell. That bell always produces the same note when it is struck.

The bell produces a waveform in the air very much like the electronic waveform produced by most electronic devices.

The note (or "pitch") produced by the bell has a 'wavelength' which is determined by how many times it vibrates in one second and how fast the signal moves away from the bell during that second. The "wavelength" is the distance travelled by the sound during the length of time which it takes for a single vibration.

In electronics, a coil of wire has a resonant frequency, just like the bell has. At that frequency, the coil will vibrate with the minimum amount of input energy possible.

The wavelength of the resonant frequency of the coil is the distance which the electronic signal travels in the length of time needed for just one cycle of it's vibration. Electronic signals generally travel at what is called 'the speed of light' and believed to be about 299,792,458 metres per second. If the coil is vibrating 30,000 times per second (30kHz), then the wavelength will be about $299,792,458 / 30,000$ metres or about 9993 metres.

As far as I know, the number quoted by Don Smith is a fixed relationship between the length of wire in a coil and the wavelength of the coil at it's resonant frequency. I am not expert in radio frequency technology, so my explanation of that number may not be fully correct.

A very good resonant ratio between the primary coil ("L1") and the secondary coil ("L2") of a Tesla Coil is 1:4 which means that the length of wire in the secondary coil should be exactly four times the length of wire in the primary coil. That automatically gives the quarter wavelength ratio without you needing to know what the actual wavelength is.

In Don's case, he takes the frequency generated by his neon-tube driver module, and uses the number which you are asking about, to calculate the length of wire in a primary coil which will require the lowest possible amount of current to make it vibrate. That is, the coil's resonant frequency of vibration will match the neon-tube driver module frequency exactly. Other wire lengths will work, but the very best length is the one which he calculates. I hope this helps in spite of the language difficulty.

Question:

in Don's air core coil builders guide he says for L2 wire length at 1/4 wave - divide 247 by frequency. in his example it works out nicely at 10ft. My transformer is from 30 to 40kHz. lets say 35kHz to be in the middle. $35\text{kHz} = 0.035\text{MHz}$ (I think). so $247 \text{ divided by } 0.035 = 7057 \text{ ft!}$ Now that's a wee tad on the long side me thinks! So I'm guessing that I can keep dividing until I reach a realistic coil length? Here's the question, for L2 to be in harmony with the 35kHz transformer output should I keep dividing the 7057 by even numbers OR by 247, or am I barking up the wrong tree completely?

Answer:

I don't claim to be any kind of expert on this stuff, but this is what I understand:

The heart of a Don Smith design is a resonant transformer. That transformer runs at high frequency and so it needs to be air-core. It can be either step-up or step-down. The lower voltage side needs wire of twice the thickness of the high voltage side. It is this transformer which is the ONLY part of the design which must be resonant and the resonance is between the two windings of that transformer, because at resonance (and not at ANY other frequency) the secondary becomes a room-temperature superconductor with no resistance at all.

To get that exact resonant match, either the length of wire in the turns of the thick-wire coil has a length which is exactly one quarter of the length of wire in the turns of the thin-wire coil OR alternatively, either or both of those coils has a capacitor placed across it so that the coil/capacitor combination has exactly the same resonant frequency of the other coil (or coil/capacitor pair if the other coil also has a capacitor wired across it).

If the two sides of that transformer are matched for resonance, then it doesn't matter what frequency is fed to the primary as the secondary will resonate with it. It is like striking a bell with a hammer. The bell has a specific resonant frequency and it will resonate at that frequency no matter how fast or how slowly it is hit with a hammer.

So, if you let your high-frequency power supply fill up a small high-voltage capacitor to some high voltage until it discharges suddenly through a spark gap (or neon or gas-filled discharge tube) and through the primary, that sudden voltage spike will generate a massive output in the superconducting secondary winding, even though the frequency of the sparks is not the resonant frequency of the primary coil.

The main problem is now encountered and that is the fact that the voltage and current in the secondary coil are ninety degrees out of phase. That means that when the voltage is high, the current is very low and when the current is very high, the voltage is very low, and so the output power appears to be very low even though it has the potential of massive output power. As I understand it, one way to overcome this is to wind the second half of the output coil in the opposite direction to the turns in the first half of the coil. That is, if the first half has clockwise turns, then the second half has counter-clockwise turns. The two ends are then joined together either with a high-voltage diode on both ends or without any diode. The output is then between the centre of the two-section coil and the two combined ends. This joining of the ends of the coil, combines the current and voltage outputs and that composite signal is then ready to drive the primary of an air-core step-down transformer to give lower voltage at higher current, ready to be rectified to DC or to have it's frequency altered by pulsing the output at the local mains frequency.

Chapter 3 has an attempt to explain this in fair detail, starting at page 46. Some people are of the opinion that the grounding wire and/or the connection to the load will alter the frequency of the secondary coil. I have no idea if that is so or not and experimentation is needed to check it out.

Good luck with your project

Topic: General Items

Question:

I was doing a web search today and came across your comprehensive book on free-energy devices. Since I've recently been introduced to this concept of the Zero-Point Energy Field, and still remain sceptical of a true Over Unity machine... I would like to ask if you have seen any such models working in person, with your own eyes? Something that runs without external energy input for an extended period of time!

If I were to replicated some of the experiments, is it easy to get in contact with those inventors? Have you been able to contact them and have had fruitful communications in the past? My curiosity is high, and I would highly appreciate your assistance!

Answer:

Thank you for your e-mail. I fully understand your caution in accepting something which you can't see and about which conventional science appears to be doubtful - calling it "dark energy".

I have met with just a very few of the people mentioned in the eBook as the internet allows us to talk freely to anyone around the world while getting together is usually VERY expensive and often almost impossible. I have met with Bob Boyce and Ed Holdgate in the USA and Dave Lawton who is in Wales. I have corresponded with many people around the world, including John Bedini, Tom Bearden, Ravi Ravu, Lawrence Tseung, Scott Cramton, Tom Thayer, Ron Pugh, Bill Williams, Lawrence Rayburn and a host of other people who have achieved $COP > 1$.

Because of the fact that people are so scattered around the world, I have only seen "with my own eyes" two $COP > 1$ electrolysis systems and one battery-charging $COP > 1$ system. After much correspondence, I have not the slightest doubt as to the complete honesty of many of the people claiming to have working devices, many of whom do not want their names published and several who do not want any details of what they have achieved, disclosed in any way.

Many people think that those who claim these things are just seeking publicity while the reality is just the reverse with most wanting to be left in peace and many quite reluctant to share the details of what they have achieved. One of my biggest problems is that most inventors are driven by curiosity and when they succeed, they lose interest and move on to something else about which they are curious, usually taking the successful device apart in order to use the components for something else, and never documenting what they did.

Dave Lawton's successful replication of Stan Meyer's "Water Fuel Cell" had reached his spares box for recycling when he happened to mention it to me when talking on the phone. I then persuaded him to let me document it, and dozens of people have, since then, made successful copies of Dave's cell. Dr Scott Cramton worked on from that document and has reached 6 litres per minute of hydroxy gas for about 36 watts of input power (which Faraday would have believed to be impossible, stating the maximum possible performance would be 842.4 watts to get 6 litres per minute).

There is no way that I could convince you of the reality of the energy field, although I might be able to persuade you on devices which have a greater output than your input (your refrigerator for example which is $COP = 3$).

Question:

I was looking through the "bedini_monopole3" Yahoo forum files for performances achieved, and most people have reported COP results of between 0.85 and 1.2 with a couple of wild results. Is this all you can get from a Simple Schoolgirl battery pulser?

If the recapture of Back EMF is central to COP success, then should we simply set up a coil, pulse it with DC, capture the Back EMF, making sure that the pulsing frequency is low enough to allow the coil to charge up? It seems too easy and too straightforward.

Answer:

The Ron Pugh Bedini pulser shown with photographs in the eBook has run at $COP = 11$ with a bank being charged from a single battery. Few people construct to that quality or tune accurately like they should. Batteries are not a great solution and a generator running on water has massively greater use to a person - you won't get any battery pulser gaining more than 4 kilowatts.

Picking up Back EMF can be relatively straightforward. Remember the man in South Africa who charges up his 10 Amp-Hour battery each night using the battery which is being charged to power the circuit which is doing the recharging. That system uses Bob Boyce's toroid plus three diodes and one small toroidal choke. At the present time, that circuit recharges at just 12 watts (i.e. 1 amp of current) which is not a massive rate of recharging, but the overall performance is spectacular as present-day science says that doing this is "impossible" and yet this man has done it more than 35 times in a row.

I have a problem with batteries. To get the sort of current supply which a household needs, an impossible number of large, expensive batteries are needed. Even if you keep the rate of discharge down to discharging over the recommended twenty hour period, those batteries will need to be replaced on a regular basis. Also, batteries are not 100% efficient and so part of the current which you feed into them will not be returned to you when you need it to power your equipment. What is really needed is some alternative system which can generate the needed

power at the time when you need it. For that reason, while I am not a fan of internal combustion engines, a generator which has been adapted to run off water alone and which provides several kilowatts of excess power, looks like a much more viable solution to off-the-grid power.

Question:

I would welcome your comments re certain passages in Chapter 5. It talks about the load being powered indefinitely. However there are certain references to discharged batteries being restored under a minute and also that the batteries would charge up to nearly 36 volts with no apparent ill effects. After the discharged battery is restored after a minute this would seem to indicate that after one minute all batteries would start being overcharged. Does this matter? Is there any danger of damage, fire or explosion? There was some mention of control circuitry to prevent over-charging. If the circuit behaved itself during trials why would control circuitry be needed? Also, would not this compromise the correct working of this system? At the moment I am only thinking of using rechargeable batteries.

Answer:

Rechargeable batteries should be ok. John Bedini's "cigar-box" demo Tesla Switch used rechargeable and it ran for six months solid until it was smashed by the opposition who then intimidated John. The section in Chapter 5 which you mention is a quotation of what the Electrodyne Corp. people reported as their experiences with their implementation of the Tesla Switch. They were using four ordinary car batteries. I don't think that lead-acid batteries have any problem with over-voltage when they have become conditioned through Tesla Switch use for a month or two. The over-voltage protection was a suggestion from me and I believe that any problems which they had with the higher voltage were most likely to do with the voltage rating of the components in their circuit rather than with the batteries themselves.

Please be aware that the Tesla Switch pulser physical layout on stripboard shown in that chapter was corrected for an error very recently and so you should download a new copy of chapter 5 (or the eBook) if you intend to build from that particular layout.

Question:

I may have missed any discussion in regards to patents, so I would like to know if these are public domain, or what, if any, restrictions are involved in making one for oneself, or selling plans, or products.

Also, do you have a recommended parts warehouse? I am in the midst of searching, and would like to buy capacitors, chokes, and diodes from the one place. Any help you can give along these lines would be appreciated.

Answer:

Patents are documents of Public Record and so may be reproduced by anybody for any purpose. You are able to make anything shown in a patent for your own use. A patent has extremely limited power and is only there as a low-grade tool against competing commercial companies trying to outsell the patent holder. They can be used by rich and powerful individuals to harass and oppose the individual inventor or very small business by wasting a massive amount of time in court - time which should have been spent in production, and wasting vast amounts of money in defending against court cases (which may well be frivolous). Even if you personally, hold a patent on some device, you would need a tremendous amount of money to fight a patent application from someone else, even though the new application is clearly based on your design. Patents are only useful for very rich people.

There are links to electronics outlets on my websites, but you don't say what country you are in. In the USA, mouser.com might be a good source, while in the UK, perhaps ESR, Maplins or RadioSpares might be your choice.

Question:

May I ask what excess energy devices are there which have no moving parts?

Answer:

There are many devices of that type, with Don Smith having about four dozen, Herman Plauson describing aerial systems of his as being "small" if their output is not over 100 kilowatts, Bob Boyce's toroid which self-charges batteries, Steven Mark's toroid, the Colman/Seddon-Gillespie 1 kW battery, and many, many more.

Mind you, the ones with no moving parts are more difficult to get working as they usually need tuning and most people don't have the necessary level of patience (and many don't have the know-how either).

Question:

It appears resonance is the key to success. Although I have a background as an electronic technician, I am a complete novice regarding "free energy". I have been reading everything I can get my hands on. If you have any other informative references please let me know.

Answer:

The problem with the information is that different people have different theories on what happens and how it happens in the free-energy arena. Some people believe that it is electron spin while others believe that it is the ambient background being nudged into imbalance and others believe that the interface is through rotating magnetic fields.

It is distinctly possible that each of these views is correct and that there are several ways of tapping this energy. However, I can't point you at any one definitive text which describes it all in detail and explains how to gather and use it easily and cheaply.

We have been held back to the 1903 level of flight where flying is just not available to almost anyone. For us now, free-energy is just not available to almost anyone. Worse still, the internet is being smothered with legislation to curtail its use. Unelected people can dictate that any site is excluded from people in their country. The countries which have already implemented this are China, Australia and the UK and I think that the US is likely to do the same in the near future. I would expect my website to be in the list of excluded sites.

So, to answer your question, if I knew of any really good material on the subject, I would either have it on my web site or I would point to it. So sorry, nothing additional springs to mind.

Question:

I recently read with interest what you had to say about colloidal silver, but have I think found a problem! You state that in order to produce colloidal silver that it is necessary to use distilled water and that the silver rods are placed on opposite sides of the beaker. Well even at 27 Volts it is impossible to produce Colloidal Silver in distilled water with a electrode spacing of say 6.5 cm. So I ask, is distilled water really used or if it is anything else added?

Answer:

Highly distilled water is indeed used, and if you don't stir it, you can see streamers moving across between the electrodes. I have found the resulting colloidal silver to be very effective. Ravi in India uses the 200 cc container as he treats many people. I use a much smaller "snifter" glass whose internal dimensions are 40 mm tapering to 28 mm over a depth of 45 mm. This is because I generally use a nebuliser (or apply it externally which is really excellent for skin damage) and the dose volume needed is then very small, perhaps 8 cc or so.

I generally prepare the liquid for about 15 minutes and clean the silver oxide off the negative electrode twice in that period as it builds up very fast. The positive electrode goes non-reflective grey. I could only get much smaller diameter silver wire and so I use about eight strands on each side, bent back on itself in a vertical bundle, in order to get greater surface area.

Question:

There are so, so many areas of possible research that the challenge, for me anyway, is just in making the decision on what to try. There are two that I think I'd like to take a stab at:

1. The Tesla Switch.
2. The Stephan Leben circuit (base upon the original of Alexander Meissner).

However, I have a question concerning each of them. For the Tesla Switch, I've read that an electro-mechanical switch is preferred (and maybe necessary for the highest potential for bringing in radiant energy). In searching a switch of this type I could not find much online to help direct me, so can you suggest a possible component here?

For the Leben/Meissner circuit, what would be a likely choice for the transistor? (That is the only component that was not named, of all the parts listed).

I would have preferred to just dig in and try these two on my own, but since my electronics background is practically nil (with the exception of assembling a Xenon strobe light circuit from a kit many years ago) I was hoping you might take some pity on this poor physics-challenged soul and offer a couple of pointers. Any information you may provide in this regard will be most appreciated. Thank you, in advance.

Answer:

Thank you for your e-mail. Chapter 12 is supposed to give you enough electronics background to allow you to understand and build circuits of this kind. If it has not done that for you, then please give me a steer as to what more is needed and I will expand the chapter accordingly. (This is a genuine request on my part and is not meant to have any kind of negative connotations.)

The phrase electro-mechanical switch does not ring an immediate bell with me but the term implies that it is a mechanical switch which is activated electrically. That would include relays and the mechanical motor-driven switch shown as being what the Electrodyne Corp. staff used (it seems likely that Don Kelly was one of those Electrodyne Corp. people). Transistors were used in John Bedini's circuit replication which ran solidly for six months before it was smashed and he was intimidated into silence.

The reason why mechanical switching is sometimes recommended is because many people do not know how to get fast switching with semiconductors. The Tesla Switch circuit needs to have all the components working together and so even the diameter and length of the connecting wires can make a difference. It is a circuit where heavy loads will work better than tiny test loads as cold electricity operates the reverse of hot electricity and so the heavier the load, the better it works. It is one of the most difficult circuits to get working well, so you might be better off picking a different project.

I think that it is unlikely that the transistor in the Leben circuit is at all critical. Technically, it needs to be able to handle the current, and that will depend on the wire size you use and the number of turns (and to a lesser degree, on the frequency which is determined by the size of the capacitor). An MJ11016 is a powerful, high-gain transistor which should work well. A BD243C transistor is popular in circuits of this type although it has a much lower gain. Hope this helps, and good luck with your project(s).

Question:

Always been a fan of yours ever since I built my first "D18" cell which may I add is still going strong and saving me loads of money. I have a question regarding the Tesla Switch: you mention that the contacts on the discs attached to the motor are set at angles. Can you please explain in more detail.

Answer:

You are the first person I have ever come into direct contact with who has ever had any success with the "D18" Nitro Cell and I have had to classify it as a "doubtful" device because of that. If you are getting a benefit from it, then I would be delighted to change it's classification and combine with you to do a better presentation of the cell including your experiences with making and using it - if you have no objection to this, then please get back to me.

I'm sorry that you have found the switching disc details difficult to understand and I will upgrade the description in the next issue of the eBook. What I was trying to say is that each disc has one sixth of it's circumference clad in copper while the following sixth of the circumference is a non-conducting material.

As there are 360 degrees in a complete circle, one sixth of the circle covers an angle of 60 degrees, which is why 60 degrees is mentioned at the present time. I will expand the description to explain this in more detail. There is no question of the actual copper cladding (or whatever method of conducting contact that you choose to use) being itself angled in any way - it is just a case of there being three sections of the disc being conducting and having an equal sized non-conducting section on each side of the conducting sections. as the contact pairs are exactly opposite each other, this causes one pair of contacts to conduct while the pair directly opposite it is not conducting. Hope this helps and my apologies for the poor description in the eBook.

Question:

I was starting to get really interested in this Free Energy stuff, and before I found your website, I had contacted CAT (Centre for Alternative Technology, based in Wales). I presume that you have heard of them?

Anyways, I was hoping to get some information from them regarding the best renewable source of energy (I was thinking of using a small hydro scheme). I thought I'd also ask their advice on Hydroxy production. As I should have expected, they lambasted and patronised my comments so thoroughly I gave up any idea of hydroxy. If an organisation such as CAT finds hydroxy ridiculous, I couldn't believe that there was any future for Hydroxy on

demand.

Do you know of anyone that has managed to heat their home using hydroxy? and if so how? Would be interested to hear any ideas.

Answer:

The 'Chapter14.pdf' document shows ways to use hydroxy for heating - which is one of the most difficult things to use it for.

Your problem with 'CAT' is due to your not understanding the overall situation. Please don't for a moment take what I am about to say as being condescending or negative in any way as it most definitely is not intended to be.

There is a foreign State which is not answerable to anyone, based in London but it is not part of England or Britain. They have chosen the deliberately confusing name of "The Crown" (which has nothing to do with any Monarch) or the "Inner City of London". Their objective is to enslave and rob the British population without them ever realising what is happening. They are a consortium of bankers and lawyers and their biggest attack weapon is a society which they set up and own. It is called "The Law Society" and they use it to mount attacks on people who do not understand the situation.

They have set up a large number of commercial companies, each with a name intended to confuse and distract. One of their companies is called "The Ministry of Justice" and the name is intended to give the impression that it has ruling powers, when in fact, it is no different to a company such as Ladbrokes betting shop. Other companies which it owns include every Magistrates Court, every Police Constabulary, every Local Council, "The Bank of England", etc. etc.

They bolster their illusion by having a 'parliament' where their employees appear to argue with each other and people in general are fooled into thinking that those employees are working for them, and every so often, they even get to choose which employees are hired. The reality is that all important decisions are made in accordance with whatever the owners want and those decisions bear no relationship whatsoever to the facts or the benefit of the population as a whole.

Vast amounts of money are stolen on a continuous basis, using names such as "National Debt", "Foreign Aid", "Income Tax", "Council Tax", "Value Added Tax", "Fuel Levy", "TV Licence", etc. etc. etc.

They own agencies such as CAT and under no circumstances would they ever approve the use of any fuel which you do not have to buy from them, so HHO is OUT !! I suspect, although I have no direct evidence for it, that any subsidies offered for "green" projects are arranged to funnel money into the coffers of their friends and colleagues as that would be wholly consistent with everything else that they do. They will only ever support projects which will be ineffective and expensive. Dave Lawton has suffered at their hands when he made a grant application and was then visited by two CIA operatives (and yes, the CIA does operate freely in Britain with the full approval of the government which is owned by the foreign independent State "The Crown").

So, your asking them about HHO was roughly equivalent to asking them if they would mind if you were to stab them with a large knife - not exactly a popular enquiry. They repeatedly undertake false public relations exercises to convince the population that free-energy is 'impossible' and that using an HHO booster on an engine never gives any benefits at all - both of those statements being wholly false.

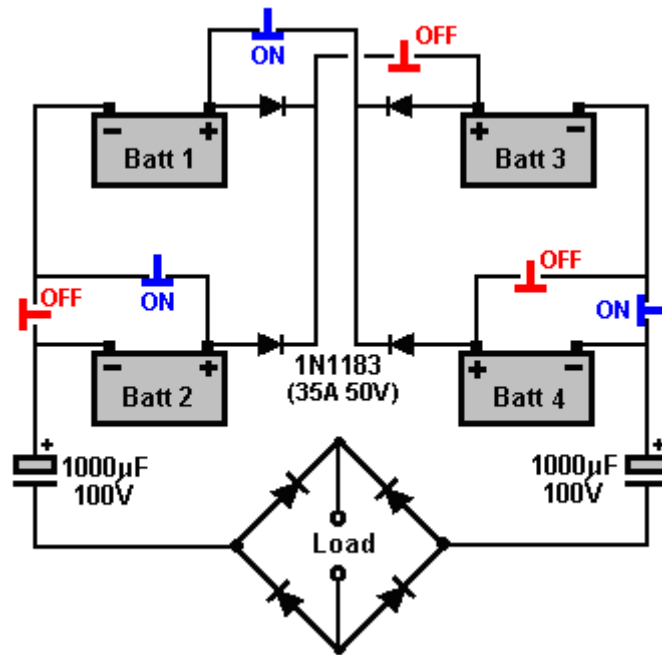

So, I would suggest that you stay away from CAT and similar companies as they are, in fact, the opposition and most definitely are not there to help you.

Question:

I have difficulty in understanding how electronic circuitry can be used to drive a Tesla Switch. Would you please show me how the components can be connected together.

Answer:

The Tesla Switch circuit used by the Electrodyne Corp. staff is shown here:

It is distinctly possible that the circuit does not reveal all the information needed for this system, as it may be necessary that the frequency at which the circuit runs needs to be a resonant harmonic of the batteries, or possibly, the load need to be a motor which generates voltage spikes. I do not know if that is the case, but I do know that the 1N1183 diodes are connected in reverse because they break down suddenly, passing a voltage spike to the batteries. It is distinctly possible that the batteries need to be conditioned for this circuit to perform the way that the Electrodyn Corp. staff reported. It should be remembered that they experimented with this and similar circuits for something like three years and it is highly likely that by the time they recorded their spectacular performances, the batteries had been very well conditioned due to the tests which they ran during those three years.

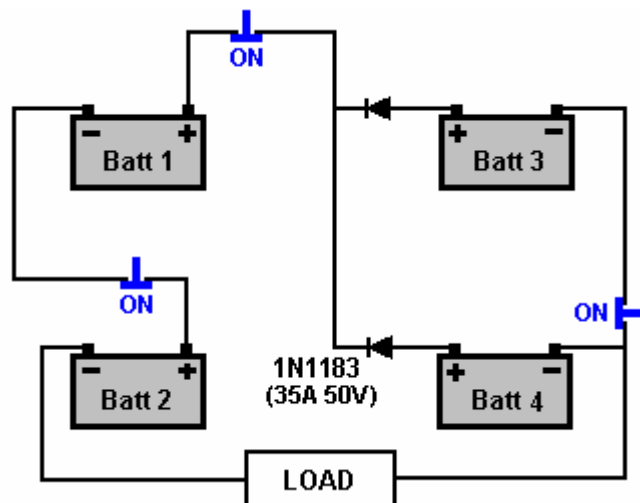

However, if I were to start experimenting with the circuit, I would show the two separate switching arrangements like this:

You will notice that each of these circuits are very direct and simple in themselves, but the “LOAD” is an essential part of the circuit and without it being in place (and able to carry current) neither circuit is completed. Personally, I would be inclined to use the 12V winding of a mains transformer as the load connection as that can handle both DC and AC current flow and the mains winding can have a bulb connected to it to show how the circuit is performing.

So, we are faced with two separate sets of three switches where each set needs to be closed when the other set is open. The question is, how can we use transistors to implement those switch operations? The difficulty is that there is no common negative voltage rail as the batteries keep getting swapped over as the circuit operates (which is the whole point of the circuit), and so, ideally, we want to switch each transistor with it connected permanently to just one battery. One circuit is:

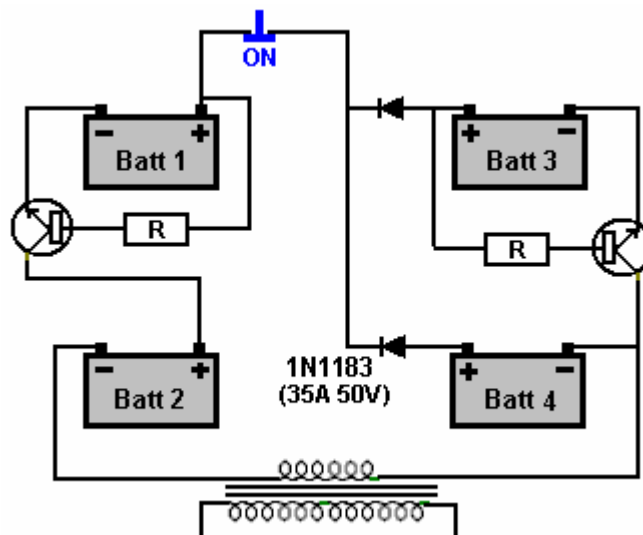

So if we were to use a transistor instead of one of the switches, we might make the circuit this:

Here, the NPN transistor base is fed a current through resistor R, and as the transistor emitter is connected to the Battery 1 Minus and the resistor is connected to the Battery 1 Plus, there will always be a voltage difference able to feed current to the transistor base, switching it fully On. Obviously, we do not leave the resistor R connected to the Battery 1 Plus all the time, but will introduce some form of solid-state switching to switch the transistor on when we want it to be on and not at other times.

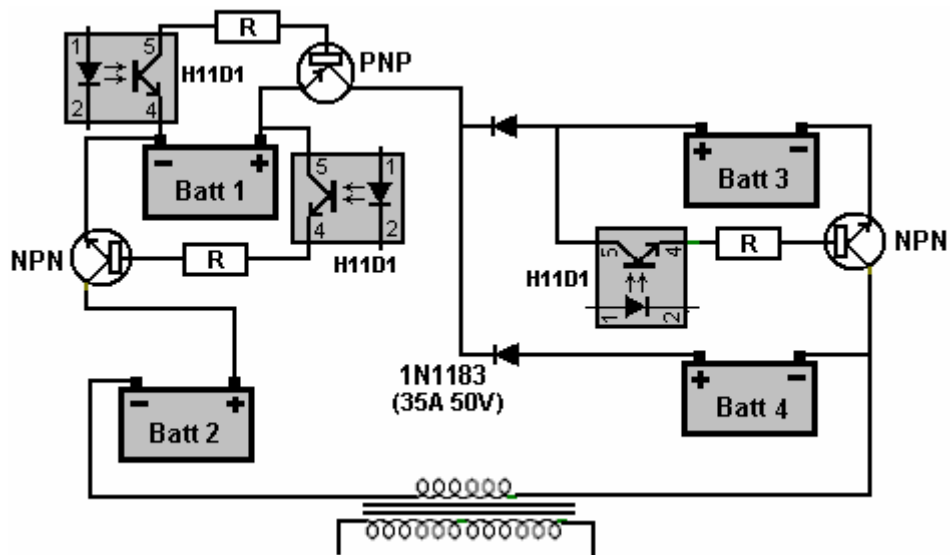

We can swap another of these switches with an NPN transistor like this:

But we now get stuck because the remaining switch does not connect to the negative side of a battery. We can get around this by using a PNP transistor as it is the mirror image of an NPN type. The circuit could then be:

This circuit will have all three transistors switched On as heavily as possible at all times. But while that does appear to substitute transistors for mechanical switches, we want to be able to turn that set of three transistors On and Off when we want. That can be achieved by making the transistor base current flow through an Opto-Isolator which can be controlled by a completely separate circuit which is not connected to this Tesla Switch circuit in any way, perhaps like this:

The opto-isolators shown here happen to be H11D1 types but many others could be used. Many different components could be used. The resistors 'R' could be, perhaps, 4.7 K, the PNP transistors MJ11015 and the NPNs MJ11016 or any high-gain, high-power transistors.

The three opto-isolators can be driven by a 555 timer signal generator which has a 50% Mark/Space ratio, perhaps like this:

The 555 timing resistor 'R' can be replaced with a fixed resistor and a variable resistor in series, so that the frequency of the switching can be adjustable. A rate of 800 Hz might be suited to this circuit. Chapter 12 has a table of the R and C values for different frequencies (perhaps 100nF and a 4.7K plus a 100K variable in this case). The other three opto isolators can be driven via an inverter IC or via a PNP fed by pin 3 of the 555 timer IC. The transistor substitution for switches for the second part of the circuit can be done in the same way.

Question:

In chapter 14 you talk about the Frenette heater, under that article you make the suggestion that one could spin magnets next to an Al plate and make heat. I do not quite understand this, is there any way you could explain a little further, or make some drawing with suggestions?

Answer:

A simple magnetic heater is just a motor with a disc mounted on it's shaft. That rotor disc has magnets mounted on it and an aluminium plates is placed beside it as shown in the diagram below. As the magnet disc spins, it causes rapidly changing magnetic currents in the aluminium which causes it to heat up. If you use an ordinary fan to blow air across the aluminium plate, you get a hot-air heater system. Having sideways "fin" plates on the aluminium sheet should improve the heat transfer to the air.

However, I have asked a man who has considerable experience in this area and he says:

Magnetic Heaters:

These are pictures of magnetic heaters which I have built and tested:

These pictures are of a magnetic heater driven by an induction motor. There are magnets placed between steel pole pieces which are adjustable to allow for the expansion caused by heating. The cylinders are made from A53 type steel. Cast iron is not suitable as the motor used spins at 3,600 rpm and cast iron has a different magnetic angle, which, while it causes a lot of resistance when being turned, slowly, does not heat up at the high speed used by me.

The steel cylinder needs to be electrically isolated from all of the other working parts of the heater and it needs to be allowed to float on the shaft so that it can increase in length as it heats up. The speed of rotation was 3,600 rpm and the cylinder was cut to a wall thickness of 0.108 inch (2.75 mm).

The colour distortion on the cylinders shown in the last photograph was caused by the heating of the cylinder when in use. These cylinders reached about 850°F and with the volume of air blown through the cylinder it produced air exhaust temperatures of 148°F. Importantly, this exiting air was ionized which provided benefits in addition to heating. Technically speaking, this ionization is actually an inefficiency.

When performing magnetic heating, the magnetic field needs to go through the metal and not along its surface as is the case in the heater shown above. Because of this, a different style of heater was built as shown here:

With this design, the magnets should not cover more than one quarter of the disc face and the magnetic field must pass all the way through each disc. Even with air being blown between the discs, the magnets get so hot that it becomes a long-term problem in that magnets lose their magnetism if raised to too high a temperature. The disc thickness is important.

There are some advantages of this type of heating mainly the motor type and power consumption allows for better than normal efficiency but that is not high enough for the construction cost to be recovered and that is why this

type of heater is not popular. However, it has the advantage that the ionization of the heated air can suppress virus and bacteria on surfaces.

It is important to note that a magnet moving over a plate heats only a small zone and the heated metal is only a narrow area within the magnetic field.

The magnetic cylinder heater shown was designed in 1989 by the late Frederick J. Galloway. Four videos have been made specifically for this query, showing the 4-kilowatt input power cylinder heater at:

<http://www.youtube.com/watch?v=JN1BXx-zXLA> Part 1 of 4

<http://www.youtube.com/watch?v=aS3SSeFbyds> Part 2 of 4

<http://www.youtube.com/watch?v=vhmQP0UStcA> Part 3 of 4

<http://www.youtube.com/watch?v=cV4Pg61wcp0> Part 4 of 4

Question:

What drawing package do you use to produce the diagrams in your eBook?

Answer:

I use the "Paint" program which comes free with Windows. As that answer upsets people, I have produced three casual videos explaining how easy it is to use. As I don't have a video camera or a phone with video facilities, these videos were produced using the FoxMagic program "Screen Virtuoso".

PERMANENT MAGNET MOTOR

This patent application shows the details of a permanent magnet motor. It should be noted that while in this text, Frank states that permanent magnets store a finite amount of magnetism, in actual fact, the magnet poles form a dipole which causes a continuous flow of energy drawn from the quantum foam of our universe, and that flow continues until such time as the dipole is destroyed. The energy which powers any permanent magnet motor comes directly from the zero-point energy field and not actually from the magnet itself. A piece of iron can be converted into a magnet by a single nanosecond magnetic pulse. It makes no sense that a pulse of that duration could provide months of continuous power from anything stored in the magnet itself, but it makes perfect sense if that brief pulse created a magnetic dipole which acts as a gateway for the inflow of zero-point energy from the environment.

ABSTRACT

A motor providing unidirectional rotational motive power is provided. The motor has a generally circular stator with a stator axis, an outer surface, and a circumferential line of demarcation at about a midpoint of the outer surface. The motor also includes one or more stator magnets attached to the outer surface of the stator. The stator magnets are arranged in a generally circular arrangement about the stator axis and generate a first magnetic field. An armature is attached to the stator so that it rotates with it, the armature having an axis parallel to the stator axis. One or more rotors, are spaced from the armature and coupled to it by an axle to allow each rotor to rotate around an axis, each rotor rotating in a plane generally aligned with the axis of the armature. Each rotor includes one or more rotor magnets, with each rotor magnet generating a second magnetic field. The second magnetic field generated by each rotor magnet interacts with the first magnetic field, to cause each rotor to rotate about the rotor axis. A linkage assembly drive connects each rotor to the stator to cause the armature to rotate about the armature axis thereby providing the unidirectional rotational motive power of the motor.

BACKGROUND OF THE INVENTION

This invention relates to dynamo electric motor structures and more particularly to rotary and linear permanent magnet motors. Conventional electric motors rely on the interaction of magnetic fields to produce a force which results in either rotary or linear motion. The magnetic fields in conventional electric motors providing rotary power, are generated by passing an externally provided electric current through conductors in either a stator (i.e. stationary portion of the motor), a rotor (i.e. rotary portion) or both the stator and the rotor. The rotary power of the motor arises from a rotating magnetic field which is created by commutating the electric current, either by a switching the current through different conductors, as in a direct current motor or by a polarity reversal of the electric current as in an alternating current motor.

It is well known that a class of materials known as ferromagnetic materials are also capable of generating a magnetic field having once been energised. Ferromagnetic materials with high coercivity are known as permanent magnets. Permanent magnets are capable of storing a finite amount of energy and retaining the ability to generate a substantial magnetic field until the stored energy is depleted.

There are electric motors which use permanent magnets in either the stator portion of the motor or the rotor portion of the motor. These motors achieve a small size for the amount of power delivered by the motor because the motors avoid having current carrying conductors to produce the magnetic field which is otherwise produced by the permanent magnets. However, these conventional permanent magnet motors still require a source of external power to produce a rotating magnetic field.

There have also been developed permanent magnet motors which use permanent magnets for both the stator and the rotor. For example, U.S. Pat. No. 4,598,221 discloses a permanent magnet motor which relies on an external source of power to rotate the magnetic fields of a rotor by ninety degrees with respect to the interacting stator magnetic fields to eliminate the counterproductive magnetic repulsion and attraction between the rotor and the stator magnets. In another example, U.S. Pat. No. 4,882,509 discloses a permanent magnet motor which relies on an external source of power to position a shield which does not permit coupling between the rotor and the stator magnets at times when attraction or repulsion would drag down the strength of the motor.

There are many instances where a motor action is required and no source of external power is available. Accordingly, a motor which relies solely on the energy stored in permanent magnets would be useful.

BRIEF SUMMARY OF THE INVENTION

Briefly stated, the present invention comprises a rotor for use in a permanent magnet motor and for providing motive power by rotation of the rotor about a rotor axis. The rotor comprises at least one first U-shaped magnet having a rear side and generating a first magnetic field. The rotation of the rotor about the rotor axis is caused by an interaction of a portion of the first magnetic field directly adjacent to the rear of the at least one U-shaped magnet with a stationary second magnetic field.

Another aspect of the present invention comprises a rotor providing motive power by a rotation of the rotor about the rotor axis and by a translation of the rotor in a direction of the rotor axis. The rotor comprises: a first U-shaped magnet having a north pole, a south pole and a rear side, the first U-shaped magnet generating a first magnetic field; a second U-shaped magnet having a north pole and a south pole, the south pole of the second U-shaped magnet abutting the north pole of the first U-shaped magnet; and a third U-shaped magnet having a north pole and a south pole, the north pole of the third U-shaped magnet abutting the south pole of the first U-shaped magnet. A portion of the first magnetic field generated by the first U-shaped magnet directly adjacent to the rear of the first U-shaped magnet interacts with a stationary fourth magnetic field to cause the rotor to rotate. A second magnetic field generated by the north pole of the second U-shaped magnet and a third magnetic field generated by the south pole of the third U-shaped magnet interact with the fourth magnetic field to cause the rotor to translate in the direction of the rotor axis.

A further aspect of the present invention comprises a rotor including a rotor axis, and a thruster axis in a plane of the rotor and intersecting the rotor axis. The rotor provides motive power by a rotation of the rotor about the rotor axis and by a translation of the rotor in a direction of the rotor axis. The rotor comprises: a first U-shaped magnet having a north pole and a south pole and a rear side, the north pole and the south pole being generally aligned with the thruster axis, the first U-shaped magnet generating a first magnetic field; a first thruster magnet having a direction of magnetisation generally aligned with the thruster magnet axis, the first thruster magnet being proximate to and spaced from the north pole of the first U-shaped magnet; and a second thruster magnet having a direction of magnetisation generally aligned with the thruster magnet axis, the second thruster magnet being near to and spaced from the south pole of the first U-shaped magnet, the first U-shaped magnet being interposed between the first and the second thruster magnets. A portion of the first magnetic field generated by the first U-shaped magnet directly adjacent to the rear side of the first U-shaped magnet interacts with a stationary fourth magnetic field to cause the rotor to rotate, a second magnetic field generated by the first thruster magnet and a third magnetic field generated by the second thruster magnet respectively interact with a stationary fifth magnetic field to cause the rotor to translate in the direction of the rotor axis.

Another aspect of the present invention comprises a rotor providing motive power by rotation of the rotor about a rotor axis and translation of the rotor in the direction of the rotor axis. The rotor has at least one rotor magnet generating a first magnetic field, the first magnetic field being generated by the rotor magnet interacting with at least one stationary U-shaped magnet, the U-shaped magnet having a rear side and generating a second magnetic field. The rotational and translational motive power of the rotor is provided by an interaction of a portion of the second magnetic field directly adjacent to the rear of the U-shaped magnet with the first magnetic field.

A further aspect of the present invention comprises a motor providing unidirectional rotational motive power. The motor includes a generally circular stator having a stator axis, an outer surface, and a circumferential line of demarcation at about a midpoint of the outer surface; at least one stator magnet attached to the outer surface of the stator, the at least one stator magnet being arranged in a generally circular arrangement about the stator axis and generating a first magnetic field; an armature attached to the stator for rotation with it; the armature having an axis parallel to the stator axis; at least one rotor, the rotor being spaced from the armature and coupled to it by an axle to allow rotation about an axis of the rotor, the rotor rotating in a plane generally aligned with the armature axis, the rotor, including at least one magnet generating a second magnetic field, where the second magnetic field generated by the rotor magnet interacts with the first magnetic field to cause the rotor to rotate about its axis; and a drive linkage assembly connecting the rotor to the stator to cause the armature to rotate about its axis as the rotor rotates about its axis, thereby providing the unidirectional rotational motive power of the motor.

In another aspect, the present invention is directed to a motor providing unidirectional rotational motive power comprising: a generally circular stator having an axis, an outer surface, and a circumferential line of demarcation around the outer surface, the line of demarcation having a pre-determined direction around the stator axis and separating a first side of the outer surface and a second side of the outer surface, wherein at least one pair of stator magnets is attached to the outer surface generating a first magnetic field, the pair of magnets comprising a first stator magnet having a north pole and a south pole and a second stator magnet having a north pole and a south pole, the south pole of the first stator magnet being located on the first side of the outer surface and the north pole of the first stator magnet being closest to the line of demarcation, the north pole of the second stator magnet being located on the second side of the outer surface and the south pole of the second stator magnet being closest to the line of demarcation, wherein the at least one pair of stator magnets is spaced along the line of demarcation so that a first inter-magnet distance measured along the line of demarcation between the north pole of the first stator magnet and the south pole of the second stator magnet of an adjacent pair of the at least one pair of stator magnets is generally equal to a second inter-magnet distance measured along the line of

demarcation between the south pole of the first stator magnet and the north pole of the second stator magnet; an armature attached to the stator, the armature having an axis parallel to the stator axis and attached to the stator for rotation therewith; and at least one rotor attached to the armature, the at least one rotor being spaced from the armature and coupled to it by an axle for rotation about an axis of the rotor, the rotor rotating in a plane generally aligned with the armature axis, the rotor comprising at least one rotor magnet, the rotor magnet generating a second magnetic field which interacts with the first magnetic field to cause the rotor to rotationally oscillate about the axis of the rotor and to generate a force in a direction of the rotor axis, thereby causing the armature to rotate in the pre-determined direction around the armature axis to provide the unidirectional rotational motive power of the motor.

In a further aspect, the present invention is directed to a motor providing unidirectional linear motive power comprising: a linear stator having a generally curved cross-section and a longitudinal line of demarcation perpendicular to the cross-section extending on about a midpoint of a surface of the stator between a first end and a second end of the stator, the stator including at least one magnet arranged between the first end and the second end, the magnet having a direction of magnetisation at about a right angle to the line of demarcation and generating a first magnetic field, the magnitude of the first magnetic field being generally uniform along the line of demarcation except in a pre-determined number of null regions, wherein the first magnetic field is substantially zero a rail connected to the stator, the rail having a longitudinal axis generally parallel to the line of demarcation and a helical groove with a pre-determined pitch running around a periphery of the rail; at least one rotor having a rotor axis aligned with the axis of the rail, the rotor being connected to the rail so that the rotor is free to rotate about the axis of the rail and slide along the rail, the rotor including at least one U-shaped magnet having a rear side and generating a second magnetic field, where a portion of the second magnetic field directly adjacent to the rear of the U-shaped magnet interacts with the first magnetic field to cause the rotor to rotate about the axis of the rail; a bearing assembly connecting the rotor to the helical groove, the bearing assembly converting the rotary motion of the rotor about the axis of the rail to linear motion along the rail; and a cross-link connecting the bearing assembly of a first rotor to a second rotor, thereby adding together the linear motion along the rail of the first rotor and the second rotor to provide the unidirectional linear motive power.

In yet another aspect, the present invention is directed to a motor providing unidirectional motive power comprising: a rail having a longitudinal axis and at least one helical groove having a pre-determined pitch running around a periphery of the rail; at least one first helical stator concentrically surrounding the rail, the first helical stator having the pre-determined pitch of the groove and a longitudinal axis generally parallel to the axis of the rail, at least one first stator magnet being attached to the first helical stator, the first stator magnet generating a first magnetic field; at least one rotor having an axis generally aligned with the axis of the rail, the rotor being connected to the rail so that the rotor is free to rotate about the axis of the rail and slide along the rail, the rotor comprising at least one rotor magnet generating a second magnetic field, the second magnetic field interacting with the first magnetic field generated by the first stator magnet to cause the rotor to rotate about the axis of the rail; and a bearing assembly connecting the rotor to the helical groove around the periphery of the rail, the bearing assembly converting the rotational motion of the rotor about the rail to unidirectional linear motion along the rail.

A further aspect of the present invention is directed to a motor providing unidirectional motive force comprising: a rail having a longitudinal axis and a helical groove running around the rail, the groove having a predetermined pitch; at least one first helical stator comprising a plurality of discontinuous spaced apart first ribs, each first rib partially surrounding the rail at a generally uniform distance from the rail, the first helical stator having the pre-determined pitch of the groove and a longitudinal axis generally aligned with the rail, at least one first stator magnet being attached to each rib, each first stator magnet generating a first magnetic field; at least one rotor having an axis generally aligned with the axis of the rail, the rotor being connected to the rail so that the rotor is free to rotate about the axis of the rail and to slide along the rail, the rotor comprising at least one rotor magnet generating a second magnetic field, the second magnetic field interacting with the first magnetic field generated by the first stator magnet to cause the rotor to rotate about the axis of the rail; and a bearing assembly connecting the rotor to the helical groove around the rail, the bearing assembly converting the rotary motion of the rotor about the rail to linear motion along the rail.

The present invention is further directed to a motor providing unidirectional motive power comprising: a rail having a longitudinal axis and a generally sinusoidal groove running around a periphery of the rail, the sinusoidal groove having a pre-determined period; at least one stator having a generally curved cross-section and a longitudinal line of demarcation perpendicular to the cross-section located at about a midpoint of a surface of the stator, the surface of the stator being disposed generally equidistant from and parallel to the axis of the rail; at least one stator magnet attached to the surface of the stator generating a first magnetic field, the stator magnet having a magnetisation which is displaced sinusoidally from the line of demarcation, the sinusoid having a pre-determined period and a pre-determined maximum amplitude and being divided into a plurality of alternating first and second sectors, with a boundary between the alternating first and second sectors occurring at the maximum amplitude of the sinusoid, the direction of magnetisation of the stator magnet being opposite in direction in the first and second segments; at least one rotor having an axis aligned with the axis of the rail, the rotor being connected to the rail so that the rotor is free to rotate about the axis of the rail and slide along the rail, the rotor including at least one U-

shaped magnet having a rear side and generating a second magnetic field, the U-shaped magnet being positioned on the rotor so that the rear side of the U-shaped magnet is apposite to the first and the second segments of the stator as the rotor rotates about the rotor axis, wherein an interaction of a portion of the second magnetic field directly adjacent to the rear of the U-shaped magnet with the first magnetic field causes the rotor to rotationally oscillate about the axis of the rail; and a bearing assembly connecting the rotor to the sinusoidal groove around the rail, the bearing assembly converting the oscillatory motion of the rotor about the rail to unidirectional linear motion along the rail.

The present invention is also directed to a motor providing unidirectional motive power comprising: a rail having a longitudinal axis and a helical groove running around a periphery of the rail, the helical groove having a pre-determined pitch; at least one stator having a generally longitudinal line of demarcation located at about a midpoint of a surface of the stator, the surface of the stator being disposed generally equidistant from and parallel to the axis of the rail; at least one stator magnet attached to the surface of the stator, the stator magnet having a direction of magnetisation which rotates about a magnetic axis parallel to the line of demarcation with a predetermined pitch, thereby generating a first magnetic field having a substantially uniform magnitude along the magnetic axis and rotates around the magnetic axis with the pre-determined pitch of the stator magnet rotation; at least one rotor having an axis aligned with the axis of the rail, the rotor being connected to the rail so that the rotor is free to rotate about the axis of the rail and slide along the rail, the rotor including at least one U-shaped magnet generating a second magnetic field, the U-shaped magnet being positioned on the rotor so that a portion of the second magnetic field directly adjacent to the rear side of the U-shaped magnet interacts with the first magnetic field of the stator magnet to cause the rotor to rotate about it's axis; and a bearing assembly connecting the rotor to the helical groove, the bearing assembly converting the rotary motion of the rotor about the rail to unidirectional linear motion along the rail.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

The foregoing summary, as well as the following detailed description of preferred embodiments of the invention, will be better understood when read in conjunction with the appended drawings. For the purpose of illustrating the invention, there are shown in the drawings embodiments which are presently preferred. It should be understood, however, that the invention is not limited to the precise arrangements and instrumentalities shown. In the drawings:

Fig.1A is a schematic perspective drawing of a first preferred embodiment of a motor providing unidirectional motive power;

Fig.1B is a schematic perspective drawing of a second preferred embodiment of the motor;

Fig.1C is a schematic perspective drawing of a third preferred embodiment of the motor;

Fig.2 is a schematic plan view of a rotor comprising three pair of U-shaped magnets;

FIG.19 is an elevational end view of the sixteenth preferred embodiment of the motor shown in Fig.18.

DETAILED DESCRIPTION OF THE INVENTION

It will be appreciated by those skilled in the art that changes could be made to the embodiments described above without departing from the broad inventive concept thereof. It is understood, therefore, that this invention is not limited to the particular embodiments disclosed, but it is intended to cover modifications within the spirit and scope of the present invention as defined by the appended claims. It should also be understood that the articles "a" and "the" used in the claims to define an element may refer to a single element or to a plurality of elements without a limit as to the number of elements.

Past attempts to construct a working permanent magnet motor have met with difficulties because of the simultaneous attractive and repulsive characteristics of a permanent magnet. A principle has been discovered where, by engaging a magnetic field at the rear of one or more U-shaped magnets mounted on a rotor with a second stationary magnetic field, a torque is created that rotates the rotor about a rotational axis of the rotor. Further, by properly shaping the second magnetic field, the rotor may be caused to also translate in the direction of the rotor axis.

Accordingly, using the aforementioned principle, and referring to **Fig.7A**, one aspect of the present invention is directed to a rotor **12** for use in a motor and which provides motive power by a rotation of the rotor **12** about a rotor axis **16** and by a translation of the rotor **12** in a direction of the rotor axis **16**. In one aspect, the rotor **12** comprises a first U-shaped magnet **20** in which the U-shaped magnet **20** generates a first magnetic field. A rotation of the rotor **12** about the rotor axis **16** is caused by an interaction of a portion of the first magnetic field directly adjacent to a rear **26** of the U-shaped magnet **20** with a stationary second magnetic field. A translation of the rotor **12** in the direction of the rotor axis **16** is caused by an interaction of the first magnetic field adjacent to a north pole **23** and a south pole **25** of the U-shaped magnet **20** with the stationary second magnetic field. As will be appreciated by those skilled in the art, the design of the rotor **12** is not limited to a single U-shaped magnet **12**. A plurality of U-shaped magnets **20**, arranged around a periphery of the rotor **12** is within the spirit and scope of the invention.

Another aspect of the present invention, shown in **Fig.7B** comprises a rotor **12** including a first U-shaped magnet having a north pole and a south pole generating a first magnetic field; a second U-shaped magnet **24** having a north pole and a south pole with the south pole of the second U-shaped magnet **24** abutting the north pole of the first U-shaped magnet **20**; and a third U-shaped magnet **22** having a north pole and a south pole with the north pole of the third U-shaped magnet **22** abutting the south pole of the first U-shaped magnet **20**. A portion of the first magnetic field generated by the first U-shaped magnet **20** directly adjacent to the rear **26** of the first U-shaped magnet **20** interacts with a stationary fourth magnetic field to cause the rotor **12** to rotate. A second magnetic field generated by the north pole of the second U-shaped magnet **24** and a third magnetic field generated by the south pole of the third U-shaped magnet **22** respectively interact with the fourth magnetic field to cause the rotor **12** to translate in the direction of the rotor axis **16**.

A further aspect of the present invention, shown in **Fig.7C**, comprises a first U-shaped magnet **20** having a north pole and a south pole generating a first magnetic field. The north pole and the south pole of the U-shaped magnet **20** are generally aligned with a thruster axis **34** which lies in the plane of the rotor **12** and intersects the rotor axis **16**. A first thruster magnet **36** is located proximate to and spaced from the north pole of the first U-shaped magnet with a direction of magnetisation being generally aligned with the thruster magnet axis **34**. A second thruster magnet **38** is located proximate to and spaced from the south pole of the first U-shaped magnet **20** with a direction of magnetisation also being generally aligned with the thruster magnet axis **34**. A portion of the first magnetic field generated by the first U-shaped magnet **20** directly adjacent to the rear side **26** of the first U-shaped magnet **20** interacts with a stationary fourth magnetic field to cause the rotor **12** to rotate. A second magnetic field generated by both the north pole and the south pole of the first thruster magnet **36** and a third magnetic field generated by both the north pole and the south pole of the second thruster magnet **38** respectively interact with a fifth magnetic field to cause the rotor **12** to translate in the direction of the rotor axis **16**. In one

further aspect of the rotor 12, as shown in **Fig.7D**, a bar magnet 43 may be substituted for the U-shaped magnet 20 and the fourth magnetic field is formed by one or more U-shaped magnets, where the bar magnet 43 interacts with a portion of the stationary fourth magnetic field adjacent to the rear of a U-shaped magnet.

As will be appreciated by those skilled in the art, the polarities of the magnets shown in **Figs. 7A, 7B, 7C and 7D** may be reversed and still be within the spirit and scope of the invention.

Referring now to **Fig.1A**, **Fig.2** and **Fig.3** there is shown a first preferred embodiment of a motor 10 using the rotor 12 and providing unidirectional rotational motive power. The first preferred embodiment comprises a generally circular stator 50 having a stator axis 72 and a circumferential surface 64 mounted to a base 18; an armature 70, having an armature axis of rotation 58 coincident with the stator axis 72, attached to the stator 50 by an armature axle 57 for rotation about the armature axis of rotation 58; and five rotors 12 (only one of which is shown for clarity), the rotors 12 being spaced at intervals of about 72 degrees around the armature 70. Each rotor 12 is spaced from the armature by an armature strut 71 and attached to the armature strut 71 by an axle, for rotation about an axis 16 of the rotor 12 in a plane generally aligned with the armature axis of rotation 58. The motor 10 further includes a driving linkage assembly 53 connecting each rotor 12 and the stator 50 together, the linkage 53 urging the armature 70 to rotate about the armature axis of rotation 58 as each rotor 12 rotates about its respective rotor axis 16. As will be appreciated by those skilled in the art the number of rotors 12 is not limited to the five rotors 12 disclosed in the first embodiment. Any number of rotors 12 from one to as many as there would be space for mounting on the armature 70 is within the spirit and scope of the invention.

Preferably, the surface 64 of the stator 50 is curved, having a curvature conforming to the arc of the rotors 12. However, it will be appreciated by those skilled in the art that the surface 64 need not be curved but could be planar and still be within the spirit and scope of the invention. As will be appreciated by those skilled in the art the stator 50 is merely intended as a stationary supporting structure for stator magnets and, as such, the shape of the stator 50 is not intended to be controlling of the size and shape of the air gap between the magnets attached to the stator 50 and the magnets attached to the rotors 12.

Preferably, the stator 50 is made of a material (or a combination of materials) having a magnetic susceptibility less than 10⁻³, i.e. a material displaying paramagnetic or diamagnetic properties. For example, the stator 50 could be

made of a non-magnetic metal such as aluminium or brass. Also, the rotor **12** could be made of a natural material such as wood, glass, a polymeric material or a combination of any of the aforementioned materials within the spirit and scope of the invention. Further, it should be understood that the aforementioned materials are preferred for the stators and all other parts of the motor **10** that could significantly disrupt the magnetic interaction between the stator and the rotor of all of the disclosed preferred embodiments of the motor **10**.

In the first preferred embodiment, the surface **64** of the stator **50** includes a circumferential line of demarcation **49** at about a midpoint of the surface **64** formed by an intersection with the surface **64** of a plane perpendicular to the armature axis of rotation **58**. As shown in **Fig.3**, the stator **50** includes a plurality of bar magnets **68** attached to the outer surface **64** along the line of demarcation **49**, except in a single null region **78** where the magnitude of the first magnetic field is substantially reduced. The bar magnets **68** have a direction of magnetisation at about a right angle to the line of demarcation **49** thereby creating a first magnetic field adjacent to the outer surface **64**, the magnitude and the direction of which is substantially uniform along the circumferential line of demarcation **49** around the axis **58** of the stator **50**, except within the null region **78**. As will be appreciated by those skilled in the art, the stator axis **72** need not be coincident with the armature axis of rotation **58**. Accordingly, a stator **50** arranged around the armature axis **58** at any location at which the stator axis **72** is parallel to the armature axis **58** and the surface **64** of the stator **50** faces the periphery of the rotors **12** thereby providing for the interaction between the first magnetic field and the second magnetic field around the armature axis **58**, is within the spirit and scope of the invention.

Preferably, as further shown in **Fig.3**, the bar magnets are attached to the surface **64** of the stator **50** so that the direction of magnetisation of the bar magnets **68** are about perpendicular to a radial line of the rotor **12**. However, the bar magnets **68** could also be attached to the surface **64** of the stator so that the direction of magnetisation of the bar magnets **68** is aligned with a radial line of the rotor **12**. The bar magnets **68** are preferably abutting so as to form the substantially uniform first magnetic field. However, it is not necessary for the bar magnets **68** to abut one another. Further, it is not necessary to use a plurality of bar magnets **68** to form the first magnetic field. A single magnet producing a uniform first magnetic field in the region in which the first magnetic field interacts with the second magnetic field of the rotors **12** would provide the required first magnetic field. Also, the number of null regions **78** may be more than one, depending upon the desired speed of the motor, as explained below.

Preferably, the stator magnets **68** are permanent magnets made of a neodymium-iron-boron material. However, as will be appreciated by those skilled in the art, any type of permanent magnet material displaying ferromagnetic properties could be used for the stator magnets **68**. For instance, stator magnets **68** made of samarium cobalt, barium ferrite or AlNiCo are within the spirit and scope of the invention. It should be understood that these permanent magnet materials or their equivalents are preferred for the stator magnets and the rotor magnets of all of the disclosed preferred embodiments of the motor **10**. Also, while the use of permanent magnets is preferred, the use of electro-magnets for some or all of the magnets is within the spirit and scope of the invention.

As discussed above, the stator **50** may include a pre-determined number of null regions **78** on the surface of the stator **64**. In the first preferred embodiment, the single null region **78** is formed by a shield of a ferromagnetic material, such as iron, placed adjacent to the surface **64**. However, as those skilled in the art will appreciate, the null region **78** can also be formed by an absence of the bar magnets **68** in the region coinciding with the null region **78**. The null region **78** of substantially reduced magnetic field magnitude may also be formed by an auxiliary magnetic field suitably generated by one or more permanent magnets or by one or more electromagnets powered by an electric current arranged so that the auxiliary magnetic field substantially cancels the first magnetic field in the null region **78**. In the case of the electromagnets, the electric current may be turned off in synchronism with the rotation of the rotors **12** passing through the null region **78**, in order to conserve power. Preferably, the first magnetic field is reduced to ten percent or less of the magnetic force outside of the null region. However, the motor **10** will operate with a reduction of only fifty percent. Accordingly, a motor **10** having a substantial reduction of the first magnetic field of fifty percent or less is within the spirit and scope of the invention.

As shown in **Fig.2**, the rotor **12** of the first preferred embodiment includes three pairs **32**, **32'**, **32''** of abutted U-shaped magnets **20** spaced apart at about 120 degree intervals around the periphery of the rotor **12**. Preferably,

the U-shaped magnets **20** having substantially identical magnetic properties and are arranged to have opposite poles of the abutting each other. The pairs **32, 32', 32''** of abutted U-shaped magnets **20** are positioned so that the north pole and the south poles of each U-shaped magnet **20** face toward the axis of the rotor **16**, and the rear side **26** of each U-shaped magnet **20**, opposite to the north and the south pole of the U-shaped magnet **20**, faces out from the axis of the rotor **16** toward the surface **64** of the stator **50**. The pairs **32, 32', 32''** of the U-shaped magnets **20** are situated on the rotor **12** so that a portion of the second magnetic field directly adjacent to the rear **26** of each U-shaped magnet **20** interacts with a first stationary magnetic field to cause the rotor **12** to rotate about its respective rotor axis **16**. Those skilled in the art will appreciate that it is not necessary to have exactly three pairs **32, 32', 32''** of U-shaped magnets **20** on the rotor **12**. For instance, the number of U-shaped magnets **20** (or groups of abutted U-shaped magnets) spaced apart around the periphery of the rotor **12** may range from merely a single U-shaped magnet **20**, up to a number of magnets limited only by the physical space around the periphery of the rotor **12**. Further, the number of abutted U-shaped magnets **20** within each group of magnets **32** is not limited to two magnets but may also range from 1 up to a number of magnets limited only by the physical space around the periphery of the rotor **12**.

Preferably, the rotor **12** is made of a material (or a combination of materials) having a magnetic susceptibility less than 10-3. Accordingly, the rotor could be made of any of the same materials used to make the stator, such as for instance, a non-magnetic metal, wood, glass, a polymeric or a combination of any of the above as shown in **Fig.1A**, the rotor **12** is preferably disk shaped with the rear **26** of the U-shaped rotor magnets **20** being arranged on the periphery of the rotor **12** in such a way that the U-shaped magnets **20** pass in close proximity to the circumferential line of demarcation **49** on the outer surface **64** of the stator **50** as the rotor **12** rotates. However, as will be clear to those skilled in the art, the structure of the rotor **12** need not be disk shaped. The rotor **12** could be a structure of any shape capable of rotating around the rotor axis **16** and capable of supporting the U-shaped magnets **20** so that, as the rotor **12** rotates, the U-shaped magnets **20** come into close proximity with the outer surface **64** of the stator **50**. For example, a rotor **12** comprised of struts connected to a central bearing, where each strut holds one or more U-shaped magnets **20**, is within the spirit and scope of the invention.

In the first preferred embodiment, the linkage **53** connecting each rotor **12** and the stator **50** comprises a beaded chain drive **60** which meshes with a stator sprocket **61** on the stator **50**, and an eccentric rotor sprocket **59** on each rotor **12** so that, as each rotor **12** rotates about its respective rotor axis **16**, the armature **70** is forced to rotate about the armature axis of rotation **58**. The eccentric rotor sprocket **59** causes the instantaneous angular velocity of the rotor **12** about the rotor axis **16** to increase above the average angular velocity of the rotor **12** as each pair **32, 32', 32''** of U-shaped magnets **20** passes through the null region **78**. As will be appreciated by those skilled in the art, the rotor sprocket **59** could be circular and the stator sprocket **61** eccentric and still cause the angular velocity of the rotor **12** to increase. Further, the beaded chain **60** in combination with the stator sprocket **61** and the eccentric rotor sprocket **59** are not the only means for connecting each rotor **12** to the stator **50**. For instance, the beaded chain **60** could also be a belt. Further, the linkage **53** could comprise a drive shaft between each rotor **12** and the stator **50**, the drive shaft having a bevel gear set at each end of the shaft mating with a bevel gear on the rotor **12** and the stator **50**. An automatic gear shift mechanism would shift gears as each U-shaped magnet pair **32, 32', 32''** entered the null regions **78** to increase the instantaneous angular velocity of the rotor **12** as the pair **32, 32', 32''** of rotor magnets **20** passed through the null region **78**. Alternatively the linkage **53** could comprise a transmission system employing elliptical gears.

While it is preferred that the instantaneous angular velocity of the rotor **12** to increase above the average angular velocity of the rotor **12** as each pair of U-shaped magnets **20** passes through the null region **78**, it is not necessary to provide the increased angular velocity of the rotor **12** to provide motive power from the motor **10**.

Preferably, the diameters of the rotor sprocket **59** and stator sprocket **61** are selected so that the rear **26** of each U-shaped magnet **20** passes through one and only one null region **78** for each full revolution of the rotor **12** about the respective rotor axis **16** as the armature **70** rotates about the armature axis of rotation **58**. Accordingly, the revolution rate of the armature **70** is related to the revolution rate of the rotor **12** by the expression:

$$S_a = (N_r / N_s) \times S_r \dots\dots\dots (1)$$

Where:

S_a is the angular velocity of the armature **70** (RPM);

N_r is the number of the U-shaped magnets **20** (or groups of abutted U-shaped magnets **32**) on a rotor **12**;

N_s is the number of null regions **12** on the stator **50**; and

S_r is the angular velocity of the rotor **12** (RPM).

The timing of the rotation of the rotor **12** around its respective rotor axis **16**, and the armature **70** about the armature axis of rotation **58** is such that each U-shaped magnet **20** (or U-shaped magnet pair **32, 32', 32''**) on each rotor **12** enters into a null region **78** at a point where the magnetic interaction between the first magnetic field

As previously discussed, the first preferred embodiment of the motor **10** comprises a single null region **78** and five rotors **12**, each rotor **12** having three pairs **32**, **32'**, **32''** of abutted U-shaped magnets **20**. Preferably, the rotors **12** are uniformly spaced around the armature axis of rotation **58** and the pairs **32**, **32'**, **32''** of U-shaped magnets **20** are uniformly spaced around the periphery of each respective rotor **12**. Further, the pairs **32**, **32'**, **32''** of U-shaped magnets **20** on each rotor **12** are phased with respect to each other by one-fifth of a revolution of the rotor **12** (i.e. the reciprocal of the number of rotors) so that the pairs **32**, **32'**, **32''** of U-shaped magnets **20** of all the rotors **12** enter the null region at substantially uniform intervals to provide a more or less continuous magnetic interaction between the first magnetic field of the stator **50** and the second magnetic field of the rotors **12**. As will be appreciated by those skilled in the art, the motive power provided by the motor is proportional to the number of rotors **12** and the number of magnets **20** on each rotor **12** as well as the strength of the rotor **12** magnets **20** and the stator **50** magnets **68**. Accordingly, the number of rotors **12** and the number of pairs **32**, **32'**, **32''** of U-shaped magnets **20** are not limited to five rotors **12** and three pairs of U-shaped magnets **32**. Similarly, the number of null regions **78** is not limited to one. The number of U-shaped magnets **20** and the number of null regions **78** are limited only by adherence to the rule established by **Equation (1)**.

Referring now to **Fig.1B**, **Fig.2** and **Fig.4** there is shown a second preferred embodiment of a motor **10** providing unidirectional rotational motive power. The second preferred embodiment comprises a generally circular stator **50'** having a stator axis **72** with magnets **68'** attached to a surface **64** of the stator **50'**; an armature **70** attached to the stator **50'** by an armature axle **57** for rotation about an armature axis of rotation **58** coincident with the stator axis **72**; and five rotors **12** (for clarity, only one of which is shown) having three pairs **32**, **32'**, **32''** of abutted U-shaped magnets **20**, the rotors **12** being spaced at intervals of about **72** degrees around the armature **70**. Each rotor **12** is spaced from the armature by a strut **71** and attached to the strut **71** by an axle for rotation in the plane of the armature axis of rotation **58** about a rotor **12** axis of rotation **16**. The motor **10** further includes a driving linkage **55** connecting each rotor **12** and the stator **50** together to cause the armature **70** to rotate about the armature axis of rotation **58** as each rotor **12** rotates about its respective rotor axis **16**.

The second preferred embodiment is identical to the first preferred embodiment except for two differences. First, instead of the first magnetic field being uniform in both magnitude and direction along the circumferential line of demarcation **49** (except in one or more null regions **78** as in the first preferred embodiment), the direction of the first magnetic field rotates about a magnetic axis parallel to the circumferential line of demarcation **49** with a pre-determined periodicity along the line of demarcation **49**. Preferably, the first magnetic field is formed from one or more stator magnets **68'** attached to the outer surface **64** of the stator **50'**, each magnet **68'** having a direction of magnetisation which causes the first magnetic field to rotate about the magnetic axis. In the second preferred embodiment, as shown in **Fig.4**, the stator magnets **68'** are equally sized bar magnets, attached to the stator **50'** so that the bar magnets **68'** spiral on the stator **50'** with the pre-determined periodicity. However, as would be apparent to those skilled in the art, the first magnetic field need not be formed by bar magnets but could be formed from a single magnet (or groups of magnets) such that the direction of magnetisation of the single magnet rotates around the magnetic axis.

The second difference between the first preferred embodiment and the second preferred embodiment is that the linkage **55** of the second preferred embodiment does not include a component for increasing the angular velocity of the rotor **12** above the average velocity of the rotor **12**. Accordingly, in the second preferred embodiment, a circular rotor sprocket **63** is used in place of the eccentric rotor socket **59**, thereby providing a constant rate of rotation of the rotor **12** about the rotor axis **16** as the armature **70** rotates about the stator **50'**.

As will be clear to those skilled in the art, the rotation of the direction of the first magnetic field around the circumferential line of demarcation **49** commutates the second magnetic field, overcoming the need for the null regions **78**. In all other respects, the operation of the second embodiment is the same as that of the first embodiment. That is, the revolution rate of each rotor **12** is related to the revolution rate of the armature **70** by **Equation (1)**, where the parameter **Ns** is the number of rotations around the line of demarcation **49** of the first magnetic field along the line of demarcation **49**. In the second preferred embodiment, as shown in **Fig.4**, the number of rotations of the first magnetic field is one. Accordingly, since there are three pairs **32**, **32'**, **32''** of U-shaped magnets **20**, each of the five rotors **12** makes one-third revolution for each full revolution of the armature **70** around the armature axis **58**. However, as will be appreciated by those skilled in the art, the motor **10** could be designed for the first magnetic field to have any number of whole periods of rotation about the armature axis **58** provided that the revolution rate of the rotors **12** was adjusted to conform to **Equation (1)**.

Referring now to **Fig.1C**, **Fig.2** and **Fig.5** there is shown a third preferred embodiment of a motor 10 providing unidirectional rotational motive power. The third preferred embodiment comprises a generally circular stator 50'' mounted to a base 18 and having an axis 72, with magnets 68'' attached to the surface 64 of the stator 50'', an armature 70 attached to the stator 50'' by an axle 57 for rotation about an armature axis of rotation 58 coincident with the stator axis 12, and five rotors 12 (for clarity, only one of which is shown) having three pairs 32, 32', 32'' of abutted U-shaped magnets 20, the rotors 12 being spaced at intervals of about 72 degrees around the armature 70. Each rotor 12 is spaced from the armature by an armature strut 71 and attached to the armature strut 71 by an axle for rotation about an axis 16 of the rotor 12 in a plane generally aligned with the armature axis 58 about

an axis **16** of the rotor **12**. The motor **10** further includes a driving linkage **62** connecting each rotor **12** and the stator **50** together to cause the armature **70** to rotate about the armature axis of rotation **58** as each rotor **12** oscillates about its respective rotor axis **16**.

The third preferred embodiment is identical to the first preferred embodiment except for three differences. First, instead of the first magnetic field being uniform in both magnitude and direction around the circumferential line of demarcation **49** (except in the null zone **78**), the first magnetic field is displaced by a sinusoidal pattern having a pre-determined peak amplitude and a pre-determined period along the circumferential line of demarcation **49**, with the direction of the first magnetic field alternating in opposite directions along the line of demarcation **49** between each peak amplitude of the sinusoidal pattern.

Preferably, as shown in **Fig.5** the first magnetic field is formed by a plurality of bar magnets **68"** arranged on the surface **64** of the stator **50"** so that the magnetisation of the bar magnets **68"** is displaced in the sinusoidal pattern from the line of demarcation **49** around the circumferential line of demarcation **49**. The sinusoidal pattern of the bar magnets **68"** is divided into first and second sectors, the boundary of which occurs at the peaks of the sinusoidal pattern. The direction of magnetisation of the bar magnets **68"** is opposite in direction in the first and the second sectors providing a commutation of the second magnetic field and causing the rotors **12** to reverse in rotational direction as the rotor **12** oscillates around the rotor axis **16** and rotates around the armature axis of rotation **58**.

Preferably, the sinusoidal pattern of the magnets has a predetermined peak amplitude so that each rotor **12** oscillates approximately +/-thirty (30) degrees from a neutral position. However, the value of the peak amplitude is not critical to the design of the motor **10**. Further, the predetermined period of the sinusoidal pattern may be selected to be any value for which the number of cycles of the sinusoidal pattern around the surface **64** of the stator **50"** is an integer value.

As will be apparent to those skilled in the art, the first magnetic field need not be formed by the bar magnets **68"** but could be formed from a single magnet (or groups of magnets) so that the first magnetic field would be sinusoidally displaced around the armature axis of rotation **58** and would alternate in opposite directions between each peak of the sinusoidal pattern. Further, as will be appreciated by those skilled in the art, the displacement of the first magnetic field need not be precisely sinusoidal. For instance the displacement may be in a shape of a sawtooth or in a shape having a portion with constant plus and minus amplitude values, within the spirit and scope of the invention.

As a result of the first magnetic field being sinusoidally displaced and alternating each one-half period, each rotor **12** oscillates through an angle corresponding to approximately the peak amplitude of the sinusoid as the rotor **12** follows the stator magnets **68"**. Accordingly, a second difference between the third embodiment and the first embodiment is in the structure of the linkage **62**. In the third preferred embodiment, shown in **Fig.1C**, the linkage **62** comprises a reciprocating rod **91** connecting each rotor **12** to a respective first gear **87** rotationally attached to the armature **70**. The reciprocating rod **91** is pivotally mounted to each rotor **12** and to each first gear **87** so that the oscillating motion of the rotor **12** is converted to rotary motion of the first gear **87**. Each first gear **87** is coupled to a single second gear **89**, attached to the stator **50** in a fixed position. The rotary motion of each first gear **87** causes the armature **70** to rotate about the armature axis of rotation **58** as the rotors **12** oscillate about the rotor axis **16**. As will be appreciated by those skilled in the art, the speed of the motor **10** is fixed by the ratio of the first gear **87** to the second gear **89** in accordance with the expression:

$$Sa = (1 / Ns) \times Sr \dots\dots\dots (2)$$

Where:

Ss is the angular velocity of the armature **70** (RPM);

Ns is the number of first magnetic field periods around the stator **50"**; and

Sr is the angular velocity of the rotor **12** (RPM).

Because each rotor **12** oscillates instead of continually rotating, only a single rotor magnet. (or group of magnets) on a given rotor **12** interacts with the single stator **50"**. Accordingly, a third difference between the third preferred embodiment and the first preferred embodiment arises because of the oscillatory motion of each rotor **12** whereby each rotor **12** of the third preferred embodiment has only a single pair of magnets **32**. However, as will be appreciated by those skilled in the art, additional stators **50"** may be added around the periphery of the rotors **12** and additional pairs of U-shaped magnets **20** may be included on each rotor **12** to interact magnetically with each additional stator **50"**, thus providing additional motive power.

Referring now to **Figs. 6, 7A, 8A and 8B**, there is shown a fourth preferred embodiment of the permanent magnet motor **10** for providing unidirectional rotational motive power. The fourth preferred embodiment comprises a generally circular stator **51** having a stator axis **72**, attached to a base **18**. The stator **51** includes an outer surface **64** divided into a first side **52** and a second side **54** by a circumferential line of demarcation **49**, having a pre-determined direction around the stator axis **72**, at about a midpoint of the outer surface **64**.

Preferably, the surface **64** of the stator **51** is curved, having a curvature conforming to the arc of the rotors **12**. However, it will be appreciated by those skilled in the art that the surface **64** need not be curved but could be planar and still be within the spirit and scope of the invention. As will be appreciated by those skilled in the art the stator **51** is merely intended as a stationary supporting structure for stator magnets and, as such, the shape of the stator is not intended to be controlling of the size and shape of the air gap between the magnets attached to the stator and the magnets attached to the rotors.

As shown in **Fig.8A**, one or more pairs of stator magnets **46** are attached to the outer surface **64** spaced along the line of demarcation **49**. Each pair of stator magnets **46** comprises a first stator magnet **40** having a north pole and a south pole and a second stator magnet **42** having a north pole and a south pole. The south pole of each first stator magnet **40**, is located on the first side **52** of the outer surface **64**, and the north pole of the first stator magnet **40** is closest to the line of demarcation **49**. The north pole of each second stator magnet **42** is located on the second side **54** of the outer surface **64** and the south pole of each second stator magnet **42** being closest to the line of demarcation **49**. The first and the second stator magnets **40**, **42** are spaced along the line of demarcation **49** so that a first inter-magnet distance measured along the line of demarcation **49** between the north pole of the first stator magnet **40** and the south pole of the second stator magnet **42** of an adjacent pair of magnets **46** is generally equal to a second inter-magnet distance measured along the line of demarcation **49'** between the south pole of the first stator magnet **40** and the north pole of the second stator magnet **42**.

In the fourth preferred embodiment, the stator magnets **40**, **42** are bar magnets. Preferably, the north pole of each first stator magnet **40** and the south pole of each second stator magnet **42** are inclined toward the pre-determined direction. Also, the bar magnets are preferably oriented on the surface **64** of the stator **50** so that the south pole of each first magnet **40** and the north pole of each second magnet **42** are nearer to the periphery of each rotor **12** than the opposite polarity pole of each of the magnets **40**, **42**. As will be appreciated by those skilled in the art, the stator magnets **40**, **42** need not be bar magnets. For instance, each stator magnet **40**, **42** could be a U-shaped magnet, or could be made up of separate magnets, as long as the first magnetic field generated by the magnets was generally equivalent to that produced by the bar magnets.

In the fourth preferred embodiment, an armature **70** having an armature axis of rotation **58** coincident with the stator axis **72** is attached to the stator **51** by an armature axle **57**, which armature axle **57** allowing the armature **70** to freely rotate about the stator axis **72**. Each rotor **12** is spaced from the armature **70** by an armature strut **71** and is mounted to the armature strut **71** so as to be free to rotate about the rotor axis **16**. The rotor axis **16** is oriented so that the rotor **12** rotates in a plane generally aligned with the armature axis of rotation **58**. In the fourth preferred embodiment, five rotors **12** are attached to the armature **70**. Preferably, the rotors **12** are uniformly spaced around the circumference of the stator **50** with a spacing of the rotors **12** as measured at the surface **64** of the stator **51** about equal to an integer multiple of twice the inter-magnet distance. However, as those skilled in the art will appreciate, it is not necessary to have the rotors **12** uniformly spaced. Further, the number of rotors **12** can be as few as one and as large as size and space constraints allow. As will be appreciated by those skilled in the art, the stator axis **72** need not be coincident with the armature axis of rotation **58**. Accordingly, a stator **50** arranged around the armature axis **58** at any location at which the stator axis **72** is parallel to the armature axis **58** and the surface of the stator **50** faces the periphery of the rotors **12**, thereby providing for the interaction between the first magnetic field and the second magnetic field around the armature axis **58**, is within the spirit and scope of the invention.

Referring now to **Fig.7A**, each rotor **12** comprises a first U-shaped magnet **20** generating a second magnetic field. The first U-shaped magnet **20** is positioned on the rotor **12** so that the north pole and the south pole of the first U-shaped magnet **20** faces toward the axis **16** of the rotor **12**, and the rear side **26** of the first U-shaped magnet **20** faces the periphery of the rotor **12**. When the rear **26** of the first U-shaped magnet **20** is adjacent to the north pole of one of the first stator magnets **40** along the line of demarcation **49**, a portion of the second magnetic field directly adjacent to the rear **26** of the first U-shaped magnet **20** interacts with a portion of the first magnetic field generated by the north pole of the first stator magnet **40** to cause the rotor **12** to rotate in a counterclockwise direction. As the rotor **12** rotates in the counterclockwise direction, a portion of the second magnetic field associated with the south pole of the first U-shaped magnet **20** interacts with a portion of the first magnetic field associated with the south pole of the first stator magnet **40**, giving rise to a force in the direction of the rotor axis **16**, repelling the U-shaped magnet **20**, and causing the rotor **12** to translate in the pre-determined direction around the stator axis. As the rotor **12** moves away from first stator magnet **40** in the pre-direction the second magnetic field adjacent to the rear **26** of the U-shaped magnet **20** interacts with the portion of the first magnetic field associated with the south pole of the second stator magnet **42** of the pair of magnets **46**, causing the rotor **12** to reverse direction and rotate in the clockwise direction. The portion of the second magnetic field associated with the north pole of the U-shaped magnet **20** then interacts with the portion of the first magnetic field associated with the north pole of the second stator magnet **42**, again giving rise to a force in the direction of the rotor axis **16**, repelling the U-shaped magnet **20** and causing the rotor **12** to translate in the pre-determined direction. An

oscillation cycle is then repeated with the second magnetic field of the rotor **12** interacting with the first magnetic field of the adjacent pair of magnets **46**. Accordingly, the rotor **12** rotationally oscillates about the respective rotor axis **16** and generates a force in the direction of the rotor axis **16**, causing the armature **70** to rotate in the pre-determined direction around the armature axis of rotation **58** to provide the unidirectional rotational motive power of the motor. As would be appreciated by those skilled in the art, the fourth embodiment is not limited to a single stator **51** and a single U-shaped magnet **20**. Additional stators having first and second stator magnets **40**, **42** arranged identically to the stator **51** to interact with corresponding U-shaped magnets spaced around the periphery of each rotor are within the spirit and scope of the invention.

Referring now to **Fig.6**, **Fig.7B** and **Fig.8A** there is shown a fifth preferred embodiment of the permanent magnet motor **10** for providing unidirectional rotary motive force. The structure and operation of the fifth preferred embodiment is similar to that of the fourth preferred embodiment except that each rotor **12** further includes a second U-shaped magnet **24** having a north pole and a south pole with the south pole of the second U-shaped magnet **24** abutting the north pole of the first U-shaped magnet **20**, and a third U-shaped magnet **22** having a north pole and a south pole, with the north pole of the third U-shaped magnet **22** abutting the south pole of the first U-shaped magnet **20**. As the rotor **12** rotates due to interaction of the portion of the second magnetic field adjacent to the rear of the U-shaped magnet **20** with the first magnetic field, a third magnetic field generated by the north pole of the second U-shaped magnet **24** and a fourth magnetic field generated by the south pole of the third U-shaped magnet **22** each interact with the first magnetic field generated by each stator magnet pair **46** to cause each rotor **12** to generate a force in the direction of the rotor axis **16**, thereby causing the armature **70** to rotate in the pre-determined direction around the axis **58** of the stator **51** to provide the unidirectional rotational motive power of the motor.

In the fifth preferred embodiment, the portion of the second magnetic field adjacent to the rear **26** of the first U-shaped magnet **20** serves to rotate the rotor **12** while the second and third U-shaped magnets **24**, **22** generate the magnetic fields providing the force in the direction of the rotor axis **16**. Accordingly, the fifth preferred embodiment is potentially more powerful than the fourth preferred embodiment. As will be appreciated by those skilled in the art, the stator magnets **40**, **42** need not be bar magnets. For instance, each stator magnet **40**, **42** could be replaced by a U-shaped magnet or could be made up of separate magnets, as long as the first magnetic field generated by the magnets was generally equivalent to that produced by the bar magnets.

FIG. 8D

Referring now to **Fig.6** and **Fig.8C** and **Fig.8D** there is shown a sixth preferred embodiment of the motor **10**. The structure and operation of the sixth preferred embodiment is identical to that of the fifth preferred embodiment except that:

- (1) The stator magnets **40'**, **42'** on the surface **64** of the stator **51'** are in a slightly different orientation;
- (2) an additional stator magnet **41** is added to each pair of stator magnets **46** and
- (3) the U-shaped magnets **22**, **24** attached to each rotor **12** are replaced with bar magnets **36**, **38**.

Specifically, and referring now to **Fig.8C**, the direction of magnetisation of each first stator magnet **40'** and each second stator magnet **42'** is aligned to be generally perpendicular to the line of demarcation **49** instead of being inclined in the pre-determined direction around the armature axis of rotation **58** as in the fifth embodiment. Also, the stator **51'** also includes a third stator magnet **41** mounted on the outer surface **64** along the line of demarcation **49** mid-way between each first stator magnet **40'** and each second stator magnet **42'**. As shown in **Fig.8C** and **Fig.8D**, the third stator magnet **41** is oriented so that the direction of magnetisation of the third magnet **41** is aligned with the axis **16** of the rotors **12**.

As shown in **Fig.8C** and **Fig.8D**, the rotor **12** used in the sixth preferred embodiment includes a first U-shaped magnet **20**, similar to that of the fifth preferred embodiment. However, in place of the second and the third U-shaped magnets **24**, **22** used in the fifth preferred embodiments, the sixth preferred embodiment includes a first thruster bar magnet **36**, spaced from and proximate to the south pole of the first U-shaped magnet **20** and generally aligned with a thruster magnet axis **34**, and a second thruster bar magnet **38**, spaced from and proximate to the north pole of the first U-shaped magnet **20** and also generally aligned with the thruster magnet axis **34**. The thruster axis **34** lies in the plane of the rotor **12** and intersects the rotor axis **16**. Similar to the fifth preferred embodiment, the interaction of the portion of the second magnetic field directly adjacent to the rear of the U-shaped magnet **20** with the first magnetic field provides the rotational force for the rotors **12**. As the rotor **12** rotates in the clockwise direction (viewed from the second end **30** of the stator **51'**), a third magnetic field generated by both the north pole and the south pole of the second thruster magnet **36** interacts with the first stator magnet **40'**, again generating a force in the direction of the rotor axis **16**. Similarly, when the rotor **12** rotates in the counterclockwise direction a fourth magnetic field generated by both the north pole and the south pole of the first thruster magnet **38** interacts with second stator magnet **42'**, generating a force in the direction of the rotor axis **16**. The result of the force in the direction of the rotor axis **16** is to cause the armature **70** to rotate in the predetermined direction around the armature axis of rotation **58** to provide the unidirectional rotational motive power of the motor **10**.

In the sixth preferred embodiment, the stator magnets **40'**, **41**, **42'** and the thruster magnets **36**, **38** are bar magnets. However, as will be appreciated by those skilled in the art, the stator magnets **40'**, **41**, **42'** and the thruster magnets **36**, **38** need not be bar magnets. For instance, each stator magnet **40'**, **42'** could be a U-shaped magnet or could be made up of separate magnets, as long as the first magnetic field generated by the magnets was generally equivalent to that produced by the bar magnets.

Referring now to **Fig.6**, **Fig.7D** and **Fig.8E** there is shown a seventh preferred embodiment of the motor **10**. The structure and operation of the seventh preferred embodiment is similar to the sixth preferred embodiment except that the third stator magnet **41'** located on the surface **64** of the stator **51''** along the line of demarcation **49** is a U-shaped magnet **41'** with the rear of the U-shaped magnet **41'** facing the rotor **12** and the direction of magnetisation being perpendicular to the line of demarcation **49**; and the U-shaped magnet **20** is replaced with a bar magnet **20'** oriented to have the direction of magnetisation aligned with a radial line of the rotor **12**. As in the sixth preferred embodiment, each stator magnet **40'**, **42'** could be a U-shaped magnet or could be made up of separate magnets, as long as the first magnetic field generated by the stator magnets **40'**, **42'** was generally equivalent to that produced by the bar magnets.

FIG. 8A

FIG. 9

FIG. 11A

Referring now to **Fig.7A**, **Fig.8A**, **Fig.8B**, **Fig.9** and **Fig.11A**, there is shown an eighth preferred embodiment of the motor **10** for providing unidirectional linear motive power. The eighth preferred embodiment comprises a linear stator **48** having a generally curved cross-section perpendicular to a longitudinal line of demarcation **49** extending on a surface **64** of the stator between a first end **28** and a second end **30** and dividing the surface **64** of the stator **48** into a first side **52** and a second side **54**. Preferably, the generally curved cross-section of the stator **48** is concave. However, it will be appreciated by those skilled in the art that the cross-section need not be concave but could be planar or even convex and still be within the spirit and scope of the invention.

The linear stator **48** is identical to the generally circular stator **51** except for the surface **64** of the stator **48** being linear in the direction of the line of demarcation **49** instead of being circular in the direction of the line of demarcation **49**.

The eighth preferred embodiment includes the first and the second stator magnets **40**, **42** (see **Fig.8A**), the location and orientation of which are virtually identical to the orientation and location of the stator magnets **40**, **42** on the circular stator **51**. Accordingly, attached to the linear stator **48** is one or more pairs of magnets **46**, each pair of stator magnets **46** generating a first magnetic field and comprising a first stator magnet **40** having a north pole and a south pole and a second stator magnet **42** having a north pole and a south pole. The south pole of

each first stator magnet **40**, is located on the first side **52** of the outer surface **64**, with the north pole of the first stator magnet **40** being closest to the line of demarcation **49**. The north pole of each second stator magnet **42** is located on the second side **54** of the outer surface **64** with the south pole of each second stator magnet **42** being closest to the line of demarcation **49**. The first and the second stator magnets **40, 42** are spaced along the line of demarcation **49** so that a first inter-magnet distance measured along the line of demarcation **49** between the north pole of the first stator magnet **40** and the south pole of the second stator magnet **42** of an adjacent pair of magnets **46** is generally equal to a second inter-magnet distance measured along the line of demarcation **49** between the south pole of the first stator magnet **40** and the north pole of the second stator magnet **42**.

In the eighth preferred embodiment, the stator magnets **40, 42** are bar magnets, the north pole of each first stator magnet **40** and the south pole of each second stator magnet **42** being inclined toward the second end **30** of the linear stator **48**. Also, as shown in **Fig.8A**, the stator magnets **40, 42** are oriented on the surface **64** of the stator **51** so that the south pole of each first magnet **40** and the north pole of each second magnet **42** are nearer to the periphery of each rotor **12** than the opposite polarity pole of each of the stator magnets **40, 42**. As will be appreciated by those skilled in the art, the stator magnets **40, 42** need not be bar magnets. For instance, each stator magnet **40, 42** could be a U-shaped magnet or could be made up of separate magnets, as long as the first magnetic field generated by the magnets was generally equivalent to that produced by the bar magnets.

The eighth preferred embodiment also includes rail **80** having a longitudinal axis located generally parallel to the line of demarcation **49** of the stator **48**. Five rotor assemblies **14** comprising a rotor **12** and a bearing assembly **84** are slidably attached to the rail **80**.

FIG. 11A

Preferably, the bearing assembly **84**, as shown in **Fig.11A**, includes a pair of first bearings **88** slidably mounted to the rail **80** and constrained to slide along the rail without any substantial rotation, by a boss **37** in each first bearing **88**, which is keyed to a longitudinal groove **35** on the rail **80**. A second bearing **90** is connected for rotation to the pair of first bearings **88** by ball bearings. The rotor **12** is attached to the second bearing **90**. Thus, the rotor **12** attached to each bearing assembly **84** is free to oscillate rotationally about the rail **80** and to generate a force along the rail **80** in the direction of the second end of the stator **30**.

Preferably, the eighth preferred embodiment includes a cross-link **94** which ties each bearing assembly **84** together by connecting together the first bearings **88** of each bearing assembly **84**, thereby adding together the linear motion along the rail **80** of each rotor **12**.

Preferably, each rotor **12** comprises one or more one rotor magnets **20**, each rotor magnet **20** generating a second magnetic field which interacts with the first magnetic field to cause the rotor **12** to oscillate rotationally about the axis of the rail **80** and to generate a force in the direction of the axis of the rail **80** to provide the unidirectional linear motive power of the motor. In the eighth preferred embodiment, each rotor **12** is substantially identical to the rotor **12** described for the fourth preferred embodiment. Accordingly, each rotor magnet comprises a first U-shaped magnet **20** having a north pole, a south pole and a rear side **26**, a first portion of the second magnetic field directly adjacent to the rear **26** of the U-shaped magnet **20** interacting with each first magnetic field to cause each rotor **12** to oscillate rotationally about the rail **80**. A second portion of the second magnetic field adjacent to the north and the south poles of the first U-shaped magnet **20** interacts with the first magnetic field to cause the rotor **12** to generate a force in the direction of the axis of the rail **80** thereby providing the unidirectional linear motive power of the motor. As would be clear to those skilled in the art, the operation of the eighth

preferred embodiment is identical to that of the fourth preferred embodiment except that the motion of the cross-linked rotors **12** is linear along the rail **80** instead of being rotational about the armature axis of rotation **58**. Accordingly, for the sake of brevity, a description of the operation of the eighth preferred embodiment is not repeated.

Referring now to **Fig.7B, Fig.8A, Fig.8B, Fig.9** and **Fig.11A** there is shown a ninth preferred embodiment of the motor **10** for providing unidirectional linear motive power. As would be apparent to those skilled in the art, the structure and the operation of the ninth preferred embodiment is virtually identical to that of the fifth preferred embodiment except that the motion of the cross-linked rotors **12** is linear instead of rotational about the armature axis of rotation **58**. Accordingly, for the sake of brevity, a description of the structure and the operation of the ninth preferred embodiment is not repeated.

Referring now to **Figs. 7C, 8C, 8D, 9** and **11A** there is shown a tenth preferred embodiment of the motor **10** for providing unidirectional linear motive power. As would be apparent to those skilled in the art, the structure and the operation of the tenth preferred embodiment is virtually identical to that of the sixth preferred embodiment except that the motion of the cross-linked rotors **12** is linear instead of rotational about the armature axis of rotation **58**. Accordingly, for the sake of brevity, the operation of the tenth preferred embodiment is not repeated.

Referring now to **Figs. 7D, 8C, 8E, 9** and **11A** there is shown an eleventh preferred embodiment of the motor **10** for providing unidirectional linear motive power. The structure and operation of the eleventh preferred embodiment is virtually identical to the seventh preferred embodiment except that the motion of the cross-lined rotors **12** is linear instead of rotational about the armature axis of rotation **58**. Accordingly, for the sake of brevity, the operation of the tenth preferred embodiment is not repeated.

FIG. 10

Referring now to **Fig.2**, **Fig.3**, **Fig.10** and **Fig.11B**, there is shown a twelfth preferred embodiment of the motor **10** for providing linear motive power. As shown in **Fig.10**, the twelfth preferred embodiment comprises a linear stator **47** having a generally curved cross-section perpendicular to a line of demarcation **49'** extending along a midpoint of the stator **47** between a first end **28** and a second end **30** of the linear stator **47**, a rail **80'** connected to the linear stator **47** having an axis generally parallel to the line of demarcation **49'**, one or more rotor assemblies **14'** comprising rotors **12** connected to the rail **80'** by a bearing assembly **84'**, and a cross-link **94'** connecting together the linkages **84'** of adjacent rotors **12**. Preferably, the generally curved cross section of the stator **47** is concave, having a curvature conforming to the arc of the rotors **12**. However, it will be appreciated by those skilled in the art that the generally curved cross-section need not be concave but could be planar or even convex and still be within the spirit and scope of the invention.

As shown in **Fig.3**, the linear stator **47** includes one or more magnets **68** arranged on the surface **64** of the linear stator **47**, each magnet **68** having a direction of magnetisation directed at about a right angle to the line of demarcation **49'** and resulting in a first magnetic field directed generally at a right angle to the line of demarcation **49'**. The magnitude of the first magnetic field is generally uniform except in the null region **78**, in which the magnitude of the first magnetic field is substantially reduced. The linear stator **47** of the twelfth preferred embodiment is virtually identical to the circular stator **50** of the first preferred embodiment except the linear stator **50** is linear in the direction of the line of demarcation **49'** instead of being circular around the armature axis of rotation **58**. Also, the arrangement of the magnets **68** on the surface **64** of the stator **47** and the structure of the null region(s) **78** is the same as for the first preferred embodiment, as shown in **Fig.3** and as fully described in the discussion of the first embodiment. Accordingly, for the sake of brevity, a more detailed description of the structure of the linear stator **47** is not repeated.

The rotors **12** of the twelfth preferred embodiment each have an axis of rotation **16** which is aligned with an axis of the rail **80'**. The rotors **12** are connected to the rail **80'** by the bearing assembly **84'** so that each rotor **12** is free to rotate about the rail **80'** and to slide along the rail **80'**. Preferably, as shown in **Fig.2**, each rotor **12** includes three pairs of U-shaped magnets **32**, **32**, **32'**, each U-shaped magnet having a rear side **26** and generating a second magnetic field. A portion of the second magnetic field adjacent to the rear-side **26** of each U-shaped magnet **20** interacts with the first magnetic field to cause each rotor **12** to rotate about the axis of the rail **80**. The rotors **12** of the twelfth preferred embodiment are the same as the rotors in the first preferred embodiment, as described in **Fig.2** and fully discussed above. Accordingly, for the sake of brevity, the detailed description of the rotors **12** is not repeated.

FIG. 11B

As shown in **Fig.11B**, the rail **80'** has a helical groove **86** with a pre-determined pitch (i.e., turns/unit length) running around a periphery of the rail **80'**. The bearing assembly **84'** connects each rotor **12** to the helical groove **86**, converting the rotational motion of each rotor **12** around the rail **80'** to the linear motion along the rail **80'**. As shown in **Fig.11B**, the bearing assembly **84'** comprises a pair of first bearings **88'** mounted to the rail **80'** and constrained to slide along the rail **80'** without any substantial rotation, and a second bearing **90'**, mounted to an outer surface the first bearing **88'** for receiving the rotor **12**. Preferably, each first bearing **88'** has a boss **37** which engages a longitudinal groove **35** so that each first bearing **88'** slides on the rail **80'** without rotation as the second bearing **90'** rotates on the first bearings **88'**. It will be appreciated by those skilled in the art, other methods for securing the first bearings **88'** to the rail **80'** could be employed, as for instance, by making the cross-section of the rail **80'** oblate (flattened at the poles). As in the first preferred embodiment, each rotor **12** must rotate at a rate which results in the rear of each U-shaped magnet **20** on the rotor **12** passing through one of the null regions **78** each full rotation of the rotor **12**. Accordingly, the pre-determined pitch of the helical groove **86** on the rail **80'** preferably equals:

$$Pg = (1 / Nr) \times Pr \dots\dots\dots (3)$$

Where:

Pr = the pitch of the null regions **78** (null regions/unit length);

Nr = the number of U-shaped magnets (or groups of abutted U-shaped magnets) on a rotor **12**; and

Pg = the pitch of the helical groove **86** (revolutions/unit length).

Preferably, the portions of the helical groove **86** corresponding to each null region **78** have an instantaneous pitch which is greater than the pre-determined pitch of the groove **86** for increasing the angular velocity of the each rotor **12** as each one of the pairs **32, 32', 32''** of U-shaped magnets **20** passes through one of the null regions **78**. However, as will be appreciated by those skilled in the art, it is not necessary to provide the greater instantaneous pitch in order for the motor **10** to provide motive power.

As described above, the cross-link **94'** connects the bearing assembly **84'** of adjacent rotors **12** together. As shown in **Fig.10**, the cross-link **94'** connects the first bearings **88'** of each bearing assembly **84'** to the first bearing **88'** of the adjacent bearing assemblies **84'** so that the linear motion of all the rotor assemblies **14'** are added together to provide the unidirectional linear motive power of the motor **10**.

As previously stated, the first preferred embodiment of the motor **10** comprises a single null region **78** and five rotors **12**, each rotor **12** having three pairs **32, 32', 32''** of abutted U-shaped magnets **20**. Preferably, the rotors **12** are uniformly spaced along the rail **80'** and the pairs **32, 32', 32''** of U-shaped magnets **20** are uniformly spaced around the periphery of each respective rotor **12**. Further, the pairs **32, 32', 32''** of U-shaped magnets **20** are phased with respect to each rotor **12** by one-fifth of a revolution of the rotor **12** so that the pairs **32, 32', 32''** of U-shaped magnets **20** of all the rotors **12** pass through the null region **78** at a substantially uniform rate to provide a more or less continuous interaction between the first magnetic field and the second magnetic field of the rotors **12**, resulting in a more or less continuous urging of the rotor assemblies **14'** toward the second end of the stator **47**. As will be appreciated by those skilled in the art, the motive power provided by the motor **10** is proportional to the number of rotors **12** and the number of U-shaped magnets **20** on each rotor **12**. Accordingly, the number of rotors **12** and the number of pairs **32, 32', 32''** of magnets **20** of the present invention are not limited to five rotors

FIG. 12

The thirteenth preferred embodiment further includes plurality of second helical stators **82a'**, **82b'**, **82c'** (**82'**) alternating with the first helical stators **82'** along the axis **65** of the rail **80'**, and having the pre-determined pitch of the groove **86**. Each second helical stator **82'** has mounted upon it a plurality of second stator magnets **11'** having a direction of magnetisation aligned with a radial line of the rotor **12** and having a direction of magnetisation opposite in direction to the first stator magnets **11** mounted on each of the first helical stators **82**. As a consequence of the second helical stators **82'** being located midway between the first helical stators **82**, a point at about a midpoint between each rotor magnet pair **32**, **32'**, **32''** is apposite to one of the second helical stators **82'** as each rotor **12** rotates about the axis **65** of the rail **80'** and slides along the rail **80'**.

The thirteenth preferred embodiment also includes five rotors **12**, (for clarity, only three are shown), having an axis of rotation **16** generally aligned with the longitudinal axis **65** of the rail **80'**. Each rotor **12** is connected to the rail **80'** by a bearing assembly **84'** so that the rotor **12** is free to rotate about the axis **65** of the rail **80'** and slide along the rail **80'**. Preferably, each rotor **12** includes three pairs **32**, **32'**, **32''** of U-shaped magnets **20** wherein each U-shaped magnet **20** generates a second magnetic field, a portion of which adjacent to a rear **26** of the pair of U-shaped magnets **20** interacts with the first magnetic field of each first stator magnet to cause each rotor **12** to rotate about the axis **65** of the rail **80'**.

The bearing assembly **84'** (shown in detail in **Fig.11B** and **Fig.12**) connects each rotor **12** to the helical groove **86** around the periphery of the rail **80**. The bearing assembly **84'** is similar to the bearing assembly **84'** described in the twelfth preferred embodiment except for the openings in the first bearings **88'** and in the second bearing **90'** which allow the bearing assembly **84'** past the rail mounting posts **76** as the bearing assembly **84'** moves along the rail **80'**.

The thirteenth preferred embodiment may be constructed as either a linear motor or a rotary motor. In the case of the linear motor, the axes of the rail **80'** and of each helical stator **82** are substantially straight. The rail **80'** is supported on the base **18** by rail mounting posts **76** placed at intervals along the rail **80'**. The posts **76** are situated at locations along the rail **80'** at which the rotation of the rotor **12** orients the openings in the first and second bearings **88'**, **90'** to correspond to the mounting posts **76**. Each helical stator **82a**, **82b**, **82c** is supported on the base by stator mounting posts **75**. The rotors **12** are connected together by a cross-link **94'** which connects the first bearings **88'** of each bearing assembly **84'** to the first bearing **88'** of the bearing assembly **84'** of an adjacent rotor **12**. In this manner, the rotational motion of each rotor assembly **14'** is added together to provide the linear motive power of the linear motor.

FIG. 14

The thirteenth preferred embodiment may also be constructed as a rotary motor **10** as shown in **Fig.14**. In this case, the axes of the rail **80'** and the helical stators **82** are configured to be circular. The circularly configured motor **10** includes an armature **70** centrally located within the perimeter of the rail **80'**. The armature **70** rotates

about an armature axis of rotation **58** connected for rotation within a motor base **18** to which the rail **80'** is also attached by mounting posts **76** (not shown). The pitch of the first and the second helical stators **82, 82'**, measured at a radius of the rail **80**, preferably equals the predetermined pitch of the helical groove **86**. The armature **70** is fixedly attached to the first bearing **88** (see **Fig.11B**) of each bearing assembly **84'** by an armature strut **71** thereby adding together the rotational motive power of each rotor assembly **14**. In order that the armature strut **71** does not interfere with the first and second helical stators **82, 82'**, the first and second helical stators **82, 82'** are made to have an opening toward the armature axis of rotation **58**.

Preferably, each first helical stator **82a, 82b, 82c** has mounted upon it a plurality of first stator magnets **11** with each stator magnet **11** having a direction of magnetisation aligned with a radial line of the rotor **12**. Preferably, the first helical stators **82** are uniformly spaced along the longitudinal axis **65** of the rail **80'** with each first helical stator **82** corresponding to one of the plurality of magnet pairs **32, 32', 32''**. Preferably, each rotor **12** is positioned on the rail **80'** so that one of the rotor magnet pairs **32, 32', 32''** is apposite to one of the corresponding first helical stators **82** as the rotor **12** rotates about the axis **65** of the rail **80** and slides along the rail **80'**. However, as those skilled in the art will appreciate, the rotor magnet pairs **32, 32', 32''** need not be directly apposite to each helical stator **82** as the rotors **12** rotate in order to generate a rotational force.

Alternatively, as will be appreciated by those skilled in the art, the motor **10** can be constructed without the second helical stator **82'**. In the simplest case the motor **10** could comprise only a single first helical stator **82** and a single rotor **12** comprising a single U-shaped magnet **20** generating the second magnetic field. The single rotor **12** is preferably positioned in the groove **86** on the rail **80'** so that the U-shaped rotor magnet **20** is continually apposite to the single first helical stator **82**. Consequently, a portion of the second magnetic field directly adjacent to a rear **26** of the U-shaped magnet **20** interacts with the first magnetic field generated by each first stator magnet **11''** mounted on the helical stator **82** to cause the rotor **12** to rotate about the axis **65** of the rail **80** and to slide along the rail **80'**. Preferably, when only a single first stator **82** set of first stators **82** is used, each first stator magnet **11''** has a direction of magnetisation oriented to be in the plane of the rotor **12** and generally perpendicular to a radial line of the rotor **12**. The north pole and the south pole of the first stator magnet **11''** are preferably spaced apart so that when one pole of the first stator magnet **11** is directly apposite to the rotor magnet **20**, the pole of opposite polarity is equally spaced from the U-shaped magnet **20** of the rotor **12**. As one skilled in the art would appreciate, a plurality of U-shaped rotor magnets **20** and corresponding first helical stators could be used. Further, as those skilled in the art will appreciate, other configurations of the rotor magnet **20** and the stator magnet **11** are possible, all of which rely on the novel attributes of the magnetic field adjacent to the rear **26** of a U-shaped rotor magnet **20**. For example, the previously described stator magnet **11''** perpendicular to the radial line of the rotor **12** could be two separate bar magnets, spaced apart, with the magnetisation of each of the two magnets aligned with a radial line of the rotor and having opposite directions of magnetisation.

Referring now to **Fig.15A** and **Fig.15B** there is shown a fourteenth preferred embodiment of the motor **10**. The fourteenth embodiment is identical in structure to the thirteenth preferred embodiment except that the stator comprises a plurality of first ribs **77a**, **77b**, **77c** (**77**) and second ribs **77a'**, **77b'**, **77c'** (**77'**) in place of the first and the second helical stators **82**, **82'** of the thirteenth embodiment. By substituting ribs **77**, **77'** for the helical stators **82**, **82'**, the attachment of the armature **70** to the rotors **12** is simplified. As those skilled in the art will appreciate, the length of the ribs **77**, **77'** may vary from as little as 45 degrees to up to 265 degrees, with the motive power of the motor **10** being proportional to the length of the ribs.

Preferably, the first and the second ribs **77**, **77'** have a pitch and a spacing that conforms to the pre-determined pitch of the rail **80'**. Further the orientation of the first and second stator magnets **11**, **11'** and of the U-shaped rotor magnets **20** would be identical to the thirteenth embodiment. Accordingly, the operation of the fourteenth embodiment is identical to that of the thirteenth embodiment and is not repeated here for the sake of brevity.

FIG. 5

FIG. 16

FIG. 17

Referring now to **Fig.5**, **Fig.16** and **Fig.17** there is shown a fifteenth preferred embodiment of the motor **10** comprising a rail **80''** having a longitudinal axis **65** and a generally sinusoidal groove **85** having a pre-determined period running around a periphery of the rail **80''**.

Preferably, the fifteenth preferred embodiment includes three generally identical stators **50''** arrayed in a circular fashion around the rail **80''**. Each stator **50''** has a surface **64** facing the rail **80''** and disposed generally equidistant from and parallel to the axis **65** of the rail **80''**. As shown in **Fig.5** and **Fig.17** each stator **50''** has a generally curved cross-section and a longitudinal line of demarcation **49** perpendicular to the cross-section and located about a midpoint of the surface **64**.

A plurality of stator magnets **68''** are attached to the surface **64** of the stator **50''** generating a first magnetic field. The stator magnets **68''** are displaced on the surface **64** in a sinusoidal pattern around the line of demarcation **49**. The sinusoidal pattern has a pre-determined period and a pre-determined maximum (peak) amplitude along the line of demarcation **49**. In the case where the rail **80''** and the longitudinal line of demarcation **49** of the stator **50''** are in a straight line, the period of the sinusoid is preferably equal to the period of the groove **85** on the rail **80**.

The sinusoidal pattern is also divided into a plurality of first and second alternating sectors with a boundary between the alternating sectors occurring at each maximum (peak) amplitude of the sinusoid. The direction of magnetisation of the stator magnets **68''** is opposite in the first and the second segments so that the direction of the first magnetic field in each first segment is opposite to the direction of the first magnetic field in each second segment. Preferably, the direction of magnetisation of the stator magnets **68''** is generally perpendicular to a radial line of the rotor **12**. Alternatively, the direction of magnetisation of the stator magnets **68''** could be generally aligned with a radial line of the rotor **12**. Further, as will be apparent to those skilled in the art, the first magnetic field need not be formed by a plurality of bar magnets but could be formed from a single magnet so that the first magnetic field would be sinusoidally displaced from the line of demarcation **49** and would alternate in opposite directions between the peaks of the sinusoid. Further, as will be appreciated by those skilled in the art, the displacement of the first magnetic field need not be precisely sinusoidal. For instance the displacement may be in a shape of a sawtooth or in a shape having a portion with constant plus and minus amplitude values, within the spirit and scope of the invention.

Preferably, the fifteenth preferred embodiment includes five rotors **12**, each rotor **12** having an axis **16** aligned with the axis of the rail **80''**. Each rotor **12** is connected to the rail **80''** by a bearing assembly **84'** so that the rotor **12** is free to rotate about the axis of the rail **65** and slide along the rail **80''**. Preferably, each rotor **12** includes three U-shaped magnet pairs **32, 32', 32''**, each pair comprising two U-shaped magnets **20**. Each U-shaped magnet **20** has a rear side and generates a second magnetic field. Each of the U-shaped magnet pairs **32, 32', 32''** is positioned on each rotor **12** so that the rear side **26** of each U-shaped magnet **20** is apposite to the first and the second segments of the sinusoidal pattern as the at least one rotor assembly **14** rotates about the rotor axis **16**, wherein an interaction of a portion of the second magnetic field directly adjacent to the rear **26** of each U-shaped magnet **20** with the first magnetic field of a corresponding stator **50''** causes the at least one rotor **12** to oscillate rotationally about the axis **65** of the rail **80''**. Those skilled in the art will appreciate that it is not necessary to have three pairs of U-shaped magnets **32, 32', 32''**. For instance, the number of U-shaped magnets **20** (or groups of abutted U-shaped magnets) spaced apart around the periphery of the rotor **12** may range from merely a single U-shaped magnet **20**, or may range in number up to a number of magnets limited only by the physical space around the periphery of the rotor **12**. Further the number of abutted U-shaped magnets **20** in a group of magnets **32** may also range from 1 up to a number of magnets limited only by the physical space around the periphery of the rotor **12**. Preferably, the number of stators **50''** equals the number of U-shaped magnet pairs **32, 32', 32''**. However, as will be appreciated by those skilled in the art, the number of stators **50''** is not limited to three but could be any number ranging upward from one, where the number of stators **50''** would preferably equal the number of U-shaped magnet pairs **32, 32', 32''**.

As shown in **Fig.16** the bearing assembly **84'** converts the oscillatory motion of the at least one rotor **12** about the rail to unidirectional linear motion along the rail **80'** by following the sinusoidal groove **85** in the rail **80'** with the boss **92** (shown in **Fig.11B**). A cross-link **94** connects the bearing assembly **84'** of adjacent rotors **12** together, thereby adding together the linear motion of each rotor assembly **14'** along the rail to provide the unidirectional linear motive power. The structure of the bearing assembly **84'** and the cross-link **94** is shown in **Fig.11B** and **Fig.12**, and the operation is identical to the linkage **84'** and the cross-link **94'** described for the twelfth embodiment. Accordingly, a detailed description of the linkage **84'** and the cross-link **94** is not repeated, for the sake of brevity.

In another aspect, the fifteenth preferred embodiment may also be configured in a circular arrangement similar to that of the fourteenth embodiment. In the fifteenth preferred embodiment, the helical stator **82'** shown in **Fig.14** is replaced with one or more curved stators **50''** spaced around the rotors **12**. In this case, the period of the sinusoidal pattern of the stator magnets is adjusted in accordance with the distance of the surface **64** of the respective stator **50''** from the armature axis of rotation **58** in order that the U-shaped magnets **20** on the rotors **12** remain apposite to the first and the second segments, as the rotors **12** slide along the rail **80''**. Accordingly, a description of those elements of circular arrangement of the fifteenth embodiment which are the same as for the linear embodiment are not repeated, for the sake of brevity.

Referring now to **Fig.4, Fig.18** and **Fig.19** there is shown a sixteenth preferred embodiment of the motor **10** for providing unidirectional motive power comprising a rail **80''** having a longitudinal axis **65** and a helical groove **86** having a pre-determined pitch, running around a periphery of the rail **80**.

Preferably, the sixteenth preferred embodiment further includes three generally identical stators **50'**, each stator **50'** having a surface **64** disposed generally equidistant from and parallel to the axis **65** of the rail **80**. Each stator **50'** has a longitudinal line of demarcation **49** located about a midpoint of the surface **64**. Preferably, a plurality of stator magnets **68'** are attached to the surface of the stator **50'** generating a first magnetic field. The plurality of stator magnets **68'** have a direction of magnetisation which rotates about a magnetic axis parallel to the line of demarcation **49**. In the case where the rail **80''** and the longitudinal line of demarcation **49** of the stator **50'** are in a straight line, the pitch of the rotation of the stator magnets **68'** is preferably equal to the pre-determined pitch of the helical groove **86** on the rail **80**.

The sixteenth embodiment further includes five rotors **12**, each rotor **12** having an axis of rotation **16** aligned with the axis **65** of the rail **80**. Each rotor **12** is connected to the rail **80** so that the rotor **12** is free to rotate about the axis **65** of the rail **80** and slide along the rail **80**. Each rotor **12** includes three pairs **32, 32', 32''** of U-shaped magnets **20** spaced around the periphery of the rotor **12**, each U-shaped magnet **20** generating a second magnetic field. The U-shaped magnets **20** are positioned on each rotor **12** so that a portion of the second magnetic field directly adjacent to the rear side **26** of the U-shaped magnet **20** interacts with the first magnetic field generated by the plurality of stator magnets **68'** to cause each rotor **12** to rotate about the rotor axis **16**. Those skilled in the art will appreciate that it is not necessary to have exactly three pairs of U-shaped magnets **32, 32', 32''**. For instance, the number of U-shaped magnets **20** (or groups of abutted U-shaped magnets) spaced apart around the periphery of the rotor **12** may range from merely a single U-shaped magnet **20**, or may range in number up to a number of U shaped magnets **20** limited only by the physical space around the periphery of the

rotor 12. Further the number of abutted U-shaped magnets 20 in a group of magnets 32 may also range from 1 up to a number of magnets limited only by the physical space around the periphery of the rotor 12.

The sixteenth embodiment also includes a bearing assembly 84' connecting each rotor 12 to the helical groove 86, the bearing assembly 84' converting the rotary motion of each rotor 12 about the rail 80' to unidirectional linear motion along the rail 80'. A cross-link 94 connects the bearing assembly 84' of adjacent rotors 12 together, thereby adding together the linear motion of each rotor assembly 14' along the rail 80' to provide the unidirectional linear motive power. The structure of the bearing assembly 84' and the cross-link 94 is shown in Fig.11B and Fig.12, is identical to the bearing assembly 84' and cross-link 94 described for the twelfth embodiment. Accordingly, a description of the linkage 84 and the cross-link 94 is not repeated, for the sake of brevity.

In another aspect of the sixteenth preferred embodiment the motor 10 may be configured in a circular arrangement similar to that of the fourteenth embodiment, as shown in Fig.14, except that the helical stator 82' shown in Fig.14 is replaced with one or more stators 50' spaced around the rotors 12. In this case, the pitch of the rotation of the plurality of stator magnets 68' is adjusted in accordance with the distance of the surface 64 of the respective stator 50' from the armature axis of rotation 58 in order that the U-shaped magnets 20 on the rotors 12 remain aligned with the plurality of stator magnets 68' as the rotors 12 rotate about the axis 65 of the rail 80' and slide along the rail 80'. Accordingly, a description of those elements of the circular arrangement of the sixteenth embodiment which are the same as for the straight line configuration are not repeated, for the sake of brevity.

It will be appreciated by those skilled in the art that changes could be made to the embodiments described above without departing from the broad inventive concept thereof. It is understood, therefore, that this invention is not limited to the particular embodiments disclosed, but it is intended to cover modifications within the spirit and scope of the present invention as defined by the appended claims.

CLAIMS

1. An apparatus (10, 10') characterised by:

at least one rotor (12) having a periphery and a rotor axis (16), the at least one rotor (12) comprising a first rotor magnet (20) producing a first magnetic field, said first rotor magnet being U-shaped and having a north pole (23), a south pole (25) and a rear side (26), the rear side (26) of the first rotor magnet being adjacent to the periphery;

an axle (80) to which the at least one rotor (12) is connected at the rotor axis (16) for rotation of the at least one rotor (12) about the rotor axis (16); and

a stationary stator (48, 51) comprising a generally curved cross-section, said stator (51) having a surface (64) opposing the periphery of the at least one rotor (12), and a longitudinal line of demarcation (49) perpendicular to the cross-section at about a midpoint of the surface, the line of demarcation (49) delineating a first side (52) of the surface from a second side (54) of the surface (64), wherein a plurality of pairs of stator magnets (40, 42) producing a second magnetic field are attached to the surface (64), each pair of stator magnets (40, 42) comprising a first stator magnet (40) having a north pole and a south pole and a direction of magnetisation substantially parallel to the surface (64), and a second stator magnet (42) having a north pole and a south pole and a direction of magnetisation substantially parallel to the surface (64), the first stator magnet (40) being on the first side of the surface (64) with the north pole of the first stator magnet being closest to the line of demarcation (49), the second stator magnet (42) being on the second side (52) of the surface with the south pole of the second stator magnet (42) being closest to the line of demarcation (49), wherein the plurality of pairs of stator magnets (40, 42) are spaced along the line of demarcation (49) so that a first inter-magnet distance measured along the line of demarcation (49) between the north pole of the first stator magnet (40) and the south pole of the second stator magnet (42) is about equal to a second inter-magnet distance measured along the line of demarcation between the south pole of the first stator magnet (40) and the north pole of the second stator magnet (42), and wherein the interaction of the first and the second magnetic fields cause the at least one rotor (12) to translate in a predetermined direction along the line of demarcation.

2. The apparatus (10, 10') of claim 1, characterised by the north pole of each first stator magnet (40) and the south pole of each second stator magnet (42) being inclined toward the predetermined direction.

3. The apparatus (10, 10') of claim 1, further characterised by the rotor (12) including a second rotor magnet (22), said second rotor magnet (24) being U-shaped and having a north pole, a south pole and a rear side, the south pole of the second rotor magnet (22) abutting the north pole of the first rotor magnet (26) and the north pole of the second rotor magnet being adjacent to the periphery, and a third rotor magnet (24), said third rotor

magnet (24) having a north pole, a south pole and a rear side, the north pole of the third rotor magnet (24) abutting the south pole of the first rotor magnet (26) and the south pole of the third rotor magnet (24) being adjacent to the periphery, said second magnet producing a third magnetic field and third magnet producing a fourth magnetic field.

4. The apparatus (10) of claim 1, characterised by the apparatus further including an armature (70) having an armature axis (58), the at least one rotor (12) being spaced from the armature (70) by an armature strut (71) and connected thereto by the axle (80) for rotation about the rotor axis (16), the at least one rotor (12) configured for rotation in a plane generally aligned with the armature axis (58), wherein the stator (51) is circular-cylindrical, with a stator axis (72) aligned with the armature axis (58).
5. The apparatus (10') of claim 1, further characterised by the stator (48) being linear, the stator (48) oriented so that the surface (64) of the stator (48) is generally parallel to the axle (80), each at least one rotor (12) being connected to the axle (80) by a bearing assembly (84) comprising a pair of first bearings (88) slidably attached to the axle (80), and a second bearing (90) connected to the pair of first bearings (88) for rotation about the first pair of bearings (88), said at least one rotor (12) being fixedly attached to the second bearing (90).
6. The apparatus (10') of claim 5, further characterised by a crosslink (94) which connects together the at least one rotors (12).
7. A apparatus (10, 10') characterised by:

at least one rotor (12) having a periphery, a rotor axis (16) and a thruster axis (34) perpendicular to the rotor axis (16) and intersecting the rotor axis (16), the at least one rotor (12) comprising spaced apart first and second rotor magnets (36, 38) having north and south poles aligned with the thruster axis (34), and a third rotor magnet (20, 20') located between the first and second rotor magnets (34, 38) on an axis generally perpendicular to the thruster axis (34), said first, second and third magnets producing a first magnetic field;

an axle (80) to which the at least one rotor (12) is connected at the rotor axis (16) for rotation of the at least one rotor (12) about the rotor axis (16); and

a stationary stator (48', 51') comprising a generally curved cross-section, said stator (48', 51') having a surface 64 opposing the periphery of the at least one rotor (12), and a longitudinal line of demarcation (49) perpendicular to the cross-section at about a midpoint of the surface (64), the line of demarcation (49) delineating a first side (52) of the surface from a second side (54) of the surface, wherein a plurality of sets of stator magnets (40', 42', 41) producing a second magnetic field are attached to the surface (64), each set of stator magnets (40', 42', 41) comprising a first stator magnet (40') having a north pole and a south pole and a direction of magnetisation substantially perpendicular to the surface (64), a second stator magnet (42') having a north pole and a south pole and a direction of magnetisation substantially perpendicular to the surface (64), and a third stator magnet (41), the third stator magnet (41) being attached to the stator (48', 51') along the line of demarcation (49) midway between the first stator magnet (40') and the second stator magnet (42'), the first stator magnet (40') being on the first side (52) of the surface with the south pole of the first stator magnet (40') being closest surface (64), the second stator magnet (42') being on the second side (54) of the surface (64) with the north pole of the second stator magnet (42') being closest to the surface (64), wherein the plurality of sets of stator magnets (40', 42', 41) are spaced along the line of demarcation (49) so that a first inter-magnet distance measured along the line of demarcation (49) between the north pole of the first stator magnet (40') and the south pole of the second stator magnet (42') of an adjacent pair of stator magnets (40', 42', 41) is about equal to a second inter-magnet distance measured along the line of demarcation (49) between the south pole of the first stator magnet (40') and the north pole of the second stator magnet (42'), wherein the interaction of the first and the second magnetic fields cause the at least one rotor (12) to translate in a predetermined direction along the line of demarcation.

8. The apparatus (10, 10') of claim 7, characterised by the third rotor magnet (20) being a U-shaped magnet and the third stator magnet (41) being a bar magnet.
9. The apparatus (10, 10') of claim 7, characterised by the third rotor magnet (20') being a bar magnet and the third stator magnet (41') being a U-shaped magnet.
10. The apparatus (10) of claim 7, characterised by the apparatus further including an armature (70) having an armature axis (58), the at least one rotor (12) being spaced from the armature (70) by an armature strut (71) and connected thereto by the axle (80) for rotation about the rotor axis (16), the at least one rotor (12) being configured for rotation in a plane generally aligned with the armature axis (58), wherein the stator (51') is circular, with a stator axis (72) aligned with the armature axis (58).

11. The apparatus (10') of claim 7, further characterised by the stator (48') being linear, the stator (48') oriented so that the surface (64) of the stator (48') is generally parallel to the axle (80), each at least one rotor (12) being connected to the axle (80) by a bearing assembly (84) comprising a pair of first bearings (88) slidably attached to the axle (80), and a second bearing (90) connected to the pair of first bearings (88) for rotation about the pair of first bearings (88), said at least one rotor (12) being fixedly attached to the second bearing (90).
12. The apparatus (10') of claim 11, further characterised by a crosslink (94) which connects together the at least one rotors (12).
13. An apparatus (10) for providing motion characterised by:

a stationary, generally circular, stator (50, 50', 50'') having a stator axis (58), an outer surface (64), and a circumferential line of demarcation (49) in a plane perpendicular to the stator axis (58) at about a midpoint of the outer surface (64);

at least one stator magnet (68, 68', 68'') attached to the outer surface (64) of the stator (50, 50', 50''), the at least one stator magnet (68, 68', 68'') being arranged in a generally circular arrangement about the stator axis (58);

an armature (70) attached to the stator (50, 50', 50'') for rotation therewith, the armature (70) having an axis parallel to the stator axis (58);

at least one rotor (12) including at least one rotor magnet (20), the at least one rotor (12) being spaced from the armature (70) by an armature strut (71) and connected thereto by an axle (80) for rotation about a rotor axis (16), the at least one rotor (12) being configured for rotation in a plane generally aligned with the stator axis (58); and

a driving linkage assembly (53, 55, 62) connecting the at least one rotor to the stator, the linkage assembly (53, 55, 62) configured to cause the armature (70) to rotate about the stator axis (58) when the at least one rotor (12) rotates about the rotor axis (16).
14. The apparatus according to claim 13 wherein a direction of magnetisation of the at least one stator magnet (68) is generally perpendicular to a radial line of the at least one rotor (12).
15. The apparatus according to claim 13 wherein a direction of magnetisation of the at least one stator magnet (68) is generally aligned with a radial line of the at least one rotor (12).
16. The apparatus according to claim 13 wherein the at least one rotor magnet (20) comprises a U-shaped magnet.
17. The apparatus according to claim 13 wherein the at least one rotor magnet (20) comprises a bar magnet and the at least one stator magnet (68) is a U-shaped magnet.
18. The apparatus according to claim 13, the at least one stator magnet (68') having a direction of magnetisation which rotates about the circumferential line of demarcation (49) with a predetermined periodicity.
19. The apparatus according to claim 13, the at least one stator magnet (68'') having a direction of magnetisation in a plane of the stator (50'') and which is displaced in a sinusoidal pattern from the line of demarcation (49), the sinusoidal pattern having a pre-determined period and a pre-determined maximum amplitude and divided into a plurality of alternating first and second sectors with a boundary between the alternating first and second sectors occurring at peak amplitudes of the sinusoid, the direction of magnetisation of the at least one magnet (68'') being opposite in direction in the first and the second segments.

PERMANENT MAGNET MOTOR

This is a re-worded extract from this Patent. It describes a motor powered solely by permanent magnets and which it is claimed can power an electrical generator.

ABSTRACT

The invention is directed to the method of utilising the unpaired electron spins in ferromagnetic and other materials as a source of magnetic fields for producing power without any electron flow as occurs in normal conductors, and to permanent magnet motors for utilising this method to produce a power source. In the practice of the invention the unpaired electron spins occurring within permanent magnets are utilised to produce a motive power source solely through the superconducting characteristics of a permanent magnet, and the magnetic flux created by the magnets is controlled and concentrated to orientate the magnetic forces generated in such a manner to produce useful continuous work, such as the displacement of a rotor with respect to a stator. The timing and orientation of magnetic forces at the rotor and stator components produced by the permanent magnets is accomplished by the proper geometrical relationship of these components.

BACKGROUND OF THE INVENTION:

Conventional electric motors employ magnetic forces to produce either rotational or linear motion. Electric motors operate on the principal that when a conductor which carries a current is located in a magnetic field, a magnetic force is exerted upon it. Normally, in a conventional electric motor, the rotor, or stator, or both, are so wired that magnetic fields created by electromagnets use attraction, repulsion, or both types of magnetic forces, to impose a force upon the armature causing rotation, or linear displacement of the armature. Conventional electric motors may employ permanent magnets either in the armature or stator components, but to date they require the creation of an electromagnetic field to act upon the permanent magnets. Also, switching gear is needed to control the energising of the electromagnets and the orientation of the magnetic fields producing the motive power.

It is my belief that the full potential of magnetic forces existing in permanent magnets has not been recognised or utilised because of incomplete information and theory with respect to atomic motion occurring within a permanent magnet. It is my belief that a presently unnamed atomic particle is associated with the electron movement of a superconducting electromagnet and the loss-less flow of currents in permanent magnets. The unpaired electron flow is similar in both situations. This small particle is believed to be opposite in charge to an electron and to be located at right angles to the moving electron. This particle must be very small to penetrate all known elements in their various states as well as their known compounds (unless they have unpaired electrons which capture these particles as they endeavour to pass through).

The electrons in ferrous materials differ from those found in most elements in that they are unpaired, and being unpaired they spin around the nucleus in such a way that they respond to magnetic fields as well as creating a magnetic field themselves. If they were paired, their magnetic fields would cancel out. However, being unpaired they create a measurable magnetic field if their spins are orientated in one direction. The spins are at right angles to their magnetic fields.

In niobium superconductors, at a critical state, the magnetic lines of force cease to be at right angles. This change must be due to establishing the required conditions for unpaired electronic spins instead of electron flow in the conductor, and the fact that very powerful electromagnets can be formed with superconductors illustrates the tremendous advantage of producing the magnetic field by unpaired electron spins rather than conventional electron flow. In a superconducting metal, wherein the electrical resistance becomes greater in the metal than the proton resistance, the flow turns to electron spins and the positive particles flow parallel in the metal in the manner occurring in a permanent magnet where a powerful flow of magnetic positive particles or magnetic flux

causes the unpaired electrons to spin at right angles. Under cryogenic superconduction conditions the freezing of the crystals in place makes it possible for the spins to continue, and in a permanent magnet the grain orientation of the magnetised material allows these spins, permitting them to continue and causing the flux to flow parallel to the metal. In a superconductor, at first the electron is flowing and the positive particle is spinning; later, when critical, the reverse occurs, i.e., the electron is spinning and the positive particle is flowing at right angles. These positive particles will thread or work their way through the electron spins present in the metal.

In a sense, a permanent magnet may be considered a room-temperature superconductor. It is a superconductor because the electron flow does not cease, and this electron flow can be made to do work through the magnetic field which it creates. Previously, this source of power has not been used because it was not possible to modify the electron flow to accomplish the switching functions of the magnetic field. Such switching functions are common in a conventional electric motor where electrical current is employed to align the much greater electron current in the iron pole pieces and concentrate the magnetic field at the proper places to give the thrust necessary to move the motor armature. In a conventional electric motor, switching is accomplished by the use of brushes, commutators, alternating current, or other means.

In order to accomplish the switching function in a permanent magnet motor, it is necessary to shield the magnetic leakage so that it will not appear as too great a loss factor at the wrong places. The best method to accomplish this is to concentrate the magnetic flux in the place where it will be the most effective. Timing and switching can be achieved in a permanent magnet motor by concentrating the flux and using the proper geometry of the motor rotor and stator to make most effective use of the magnetic fields. By the proper combination of materials, geometry and magnetic concentration, it is possible to achieve a mechanical advantage of high ratio, greater than 100 to 1, capable of producing continuous motive force.

To my knowledge, previous work done with permanent magnets, and motive devices utilising permanent magnets, have not achieved the result desired in the practice of the inventive concept, and it is with the proper combination of materials, geometry and magnetic concentration that the presence of the magnetic spins within a permanent magnet may be utilised as a motive force.

SUMMARY OF THE INVENTION:

It is an object of the invention to utilise the magnetic spinning phenomenon of unpaired electrons occurring in ferromagnetic material to produce the movement of a mass in a unidirectional manner so as to permit a motor to be driven solely by the magnetic forces occurring within permanent magnets. Both linear and rotational types of motor may be produced. It is an object of the invention to provide the proper combination of materials, geometry and magnetic concentration to power a motor. Whether the motor is a linear type or a rotary type, in each instance the "stator" may consist of several permanent magnets fixed relative to each other, to create a track. This track is linear for a linear motor and circular for a rotary motor. An armature magnet is carefully positioned above this track so that an air gap exists between it and the track. The length of the armature magnet is defined by poles of opposite polarity, and the longer axis of the armature magnet is pointed in the direction of its movement.

The stator magnets are mounted so that all the same poles face the armature magnet. The armature magnet has poles which are both attracted to and repelled by the adjacent pole of the stator magnets, so both attractive and repulsive forces act upon the armature magnet to make it move.

The continuing motive force which acts on the armature magnet is caused by the relationship of the length of the armature magnet to the width and spacing of the stator magnets. This ratio of magnet and magnet spacings, and with an acceptable air gap spacing between the stator and armature magnets, produces a continuous force which causes the movement of the armature magnet.

In the practice of the invention, movement of the armature magnet relative to the stator magnets results from a combination of attractive and repulsive forces between the stator and armature magnets. By concentrating the magnetic fields of the stator and armature magnets the motive force imposed upon the armature magnet is intensified, and in the disclosed embodiments, the means for achieving this magnetic field concentration are shown.

This method comprises of a plate of high magnetic field permeability placed behind one side of the stator magnets and solidly engaged with them. The magnetic field of the armature magnet may be concentrated and directionally oriented by bowing the armature magnet, and the magnetic field may further be concentrated by shaping the pole ends of the armature magnet to concentrate the magnet field at a relatively limited surface at the armature magnet pole ends.

Preferably, several armature magnets are used and these are staggered relative to each other in the direction their movement. Such an offsetting or staggering of the armature magnets distributes the impulses of force

imposed upon the armature magnets and results in a smoother application of forces to the armature magnet producing a smoother and more uniform movement of the armature component.

In the rotary embodiment of the permanent magnet motor of the invention the stator magnets are arranged in a circle, and the armature magnets rotate about the stator magnets. A mechanism is shown which can move the armature relative to the stator and this controls the magnitude of the magnetic forces, altering the speed of rotation of the motor.

BRIEF DESCRIPTION OF THE DRAWINGS

The objects and advantages of the invention mentioned earlier, will be appreciated from the following description and accompanying drawings:

- Fig. 1** is a schematic view of electron flow in a superconductor indicating the unpaired electron spins,
- Fig. 2** is a cross-sectional view of a superconductor under a critical state illustrating the electron spins,
- Fig. 3** is a view of a permanent magnet illustrating the flux movement through it,
- Fig. 4** is a cross-sectional view illustrating the diameter of the magnet of Fig.3,
- Fig. 5** is an elevational representation of a linear motor embodiment of the permanent magnet motor of the invention illustrating one position of the armature magnet relative to the stator magnets, and indicating the magnetic forces imposed upon the armature magnet,
- Fig. 6** is a view similar to Fig.5 illustrating displacement of the armature magnet relative to the stator magnets, and the influence of magnetic forces thereon at this location,
- Fig. 7** is a further elevational view similar to Fig.5 and Fig.6 illustrating further displacement of the armature magnet to the left, and the influence of the magnetic forces thereon,
- Fig. 8** is a top plan view of a linear embodiment of the inventive concept illustrating a pair of armature magnets in linked relationship disposed above the stator magnets,
- Fig. 9** is a diametrical, elevational, sectional view of a rotary motor embodiment in accord with the invention as taken along section IX-IX of Fig.10, and
- Fig. 10** is an elevational view of the rotary motor embodiment as taken along X-X of Fig.9.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In order to better understand the theory of the inventive concept, reference is made to **Figs. 1 through 4**. In **Fig.1** a superconductor 1 is illustrated having a positive particle flow as represented by arrow 2, the unpaired electrons of the ferrous conductor 1 spin at right angles to the proton flow in the conductor as represented by the spiral line and arrow 3. In accord with the theory of the invention the spinning of the ferrous unpaired electrons results from the atomic structure of ferrous materials and this spinning atomic particle is believed to be opposite in charge and located at right angles to the moving electrons. It is assumed to be very small in size capable of penetrating other elements and their compounds unless they have unpaired electrons which capture these particles as they endeavour to pass through.

The lack of electrical resistance of conductors at a critical superconductor state has long been recognised, and superconductors have been utilised to produce very high magnetic flux density electromagnets. **Fig.2** represents a cross section of a critical superconductor and the electron spins are indicated by the arrows 3. A permanent magnet may be considered a superconductor as the electron flow therein does not cease, and is without resistance, and unpaired electric spinning particles exist which, in the practice of the invention, are utilised to produce motor force. **Fig.3** illustrates a horseshoe shaped permanent magnet at 4 and the magnetic flux through it is indicated by arrows 5, the magnetic flow being from the south pole to the north pole and through the magnetic material. The accumulated electron spins occurring about the diameter of the magnet 5 are represented at 6 in

Fig.4, and the spinning electron particles spin at right angles in the iron as the flux travels through the magnet material.

By utilising the electron spinning theory of ferrous material electrons, it is possible with the proper ferromagnetic materials, geometry and magnetic concentration to utilise the spinning electrons to produce a motive force in a continuous direction, thereby resulting in a motor capable of doing work.

It is appreciated that the embodiments of motors utilising the concepts of the invention may take many forms, and in the illustrated forms the basic relationships of components are illustrated in order to disclose the inventive concepts and principles. The relationships of the plurality of magnets defining the stator 10 are best appreciated from **Figs. 5 through 8**. The stator magnets **12** are preferably of a rectangular configuration, **Fig.8**, and so magnetised that the poles exist at the large surfaces of the magnets, as will be appreciated from the N (North) and S (South) designations. The stator magnets include side edges **14** and **16** and end edges **18**. The stator magnets are mounted upon a supporting plate **20**, which is preferably of a metal having a high permeability to magnetic fields and magnetic flux such as that available under the trademark Netic CoNetic sold by Perfection Mica Company of Chicago, Illinois. Thus, the plate **20** will be disposed toward the south pole of the stator magnets **12**, and preferably in direct engagement therewith, although a bonding material may be interposed between the magnets and the plate in order to accurately locate and fix the magnets on the plate, and position the stator magnets with respect to each other.

Preferably, the spacing between the stator magnets **12** slightly differs between adjacent stator magnets as such a variation in spacing varies the forces being imposed upon the armature magnet at its ends, at any given time, and thus results in a smoother movement of the armature magnet relative to the stator magnets. Thus, the stator magnets so positioned relative to each other define a track **22** having a longitudinal direction left to right as viewed in **Figs. 5 through 8**.

In **Figs. 5 through 7** only a single armature magnet **24** is disclosed, while in **Fig.8** a pair of armature magnets are shown. For purposes of understanding the concepts of the invention the description herein will be limited to the use of single armature magnet as shown in **Figs. 5 through 7**.

The armature magnet is of an elongated configuration wherein the length extends from left to right, **Fig.5**, and may be of a rectangular transverse cross-sectional shape. For magnetic field concentrating and orientation purposes the magnet **24** is formed in an arcuate bowed configuration as defined by concave surfaces **26** and convex surfaces **28**, and the poles are defined at the ends of the magnet as will be appreciated from **Fig.5**. For further magnetic field concentrating purposes the ends of the armature magnet are shaped by bevelled surfaces **30** to minimise the cross sectional area at the magnet ends **32**, and the magnetic flux existing between the poles of the armature magnet are as indicated by the light dotted lines. In like manner the magnetic fields of **6** the stator magnets **12** are indicated by the light dotted lines.

The armature magnet **24** is maintained in a spaced relationship above the stator track **22**. This spacing may be accomplished by mounting the armature magnet upon a slide, guide or track located above the stator magnets, or the armature magnet could be mounted upon a wheeled vehicle carriage or slide supported upon a non-magnetic surface or guideway disposed between the stator magnets and the armature magnet. To clarify the illustration, the means for supporting the armature magnet **24** is not illustrated and such means form no part of invention, and it is to be understood that the means supporting the armature magnet prevents the armature magnet from moving away from the stator magnets, or moving closer thereto, but permits free movement of the armature magnet to the left or right in a direction parallel to the track **22** defined by the stator magnets.

It will be noted that the length of the armature magnet **24** is slightly greater than the width of two of the stator magnets **12** and the spacing between them. The magnetic forces acting upon the armature magnet when in the position of **Fig.5** will be repulsion forces **34** due to the proximity of like polarity forces and attraction forces at **36** because of the opposite polarity of the south pole of the armature magnet, and the north pole field of the sector magnets. The relative strength of this force is represented by the thickness of the force line.

The resultant of the force vectors imposed upon the armature magnet as shown in **Fig.5** produce a primary force vector **38** toward the left, **Fig.5**, displacing the armature magnet **24** toward the left. In **Fig.6** the magnetic forces acting upon the armature magnet are represented by the same reference numerals as in **Fig.5**. While the forces **34** constitute repulsion forces tending to move the north pole of the armature magnet away from the stator magnets, the attraction forces imposed upon the south pole of the armature magnet and some of the repulsion forces, tend to move the armature magnet further to the left, and as the resultant force **38** continues to be toward the left the armature magnet continues to be forced to the left. **Fig.7** represents further displacement of the armature magnet **24** to the left with respect to the position of **Fig.6**, and the magnetic forces acting thereon are represented by the same reference numerals as in **Fig.5** and **Fig.6**, and the stator magnet will continue to move to the left, and such movement continues the length of the track **22** defined by the stator magnets **12**.

Upon the armature magnet being reversed such that the north pole is positioned at the right as viewed in **Fig.5**, and the south pole is positioned at the left, the direction of movement of the armature magnet relative to the stator magnets is toward the right, and the theory of movement is identical to that described above.

In **Fig.8** a plurality of armature magnets **40** and **42** are illustrated which are connected by links **44**. The armature magnets are of a shape and configuration identical to that of the embodiment of **Fig.5**, but the magnets are staggered with respect to each other in the direction of magnet movement, i.e., the direction of the track **22** defined by the stator magnets **12**. By so staggering a plurality of armature magnets a smoother movement of the interconnected armature magnets is produced as compared when using a single armature magnet as there is variation in the forces acting upon each armature magnet as it moves above the track **22** due to the change in magnetic forces imposed thereon. The use of several armature magnets tends to "smooth out" the application of forces imposed upon linked armature magnets, resulting in a smoother movement of the armature magnet assembly. Of course, any number of armature magnets may be interconnected, limited only by the width of the stator magnet track **22**.

In **Fig.9** and **Fig.10** a rotary embodiment embracing the inventive concepts is illustrated. In this embodiment the principle of operation is identical to that described above, but the orientation of the stator and armature magnets is such that rotation of the armature magnets is produced about an axis, rather than a linear movement being achieved.

In **Fig.9** and **Fig.10** a base is represented at **46** serving as a support for a stator member **48**. The stator member **48** is made of a non-magnetic material, such as synthetic plastic, aluminium, or the like. The stator includes a cylindrical surface **50** having an axis, and a threaded bore **52** is concentrically defined in the stator. The stator includes an annular groove **54** receiving an annular sleeve **56** of high magnetic field permeability material such as Netic Co-Netic and a plurality of stator magnets **58** are affixed upon the sleeve **56** in spaced circumferential relationship as will be apparent in **Fig.10**. Preferably, the stator magnets **58** are formed with converging radial sides as to be of a wedge configuration having a curved inner surface engaging sleeve **56**, and a convex pole surface **60**.

The armature **62**, in the illustrated embodiment, is of a dished configuration having a radial web portion, and an axially extending portion **64**. The armature **62** is formed of a non-magnetic material, and an annular belt receiving groove **66** is defined therein for receiving a belt for transmitting power from the armature to a generator, or other power consuming device. Three armature magnets **68** are mounted on the armature portion **64**, and such magnets are of a configuration similar to the armature magnet configuration of **Figs. 5 through 7**.

The magnets **68** are staggered with respect to each other in a circumferential direction wherein the magnets are not placed exactly 120 degrees apart but instead, a slight angular staggering of the armature magnets is desirable to "smooth out" the magnetic forces being imposed upon the armature as a result of the magnetic forces being simultaneously imposed upon each of the armature magnets. The staggering of the armature magnets **68** in a circumferential direction produces the same effect as the staggering of the armature magnets **40** and **42** as shown in **Fig.8**.

The armature **62** is mounted upon a threaded shaft **70** by anti-friction bearings **72**, and the shaft **70** is threaded into the stator threaded bore **52**, and may be rotated by the knob **74**. In this manner rotation of the knob **74**, and shaft **70**, axially displaces the armature **62** with respect to the stator magnets **58**, and such axial displacement will vary the magnitude of the magnetic forces imposed upon the armature magnets **68** by the stator magnets thereby controlling the speed of rotation of the armature. As will be noted from **Figs. 4 to 7, 9 and 10**, an air gap exists between the armature magnets and the stator magnets and the dimension of this spacing, effects the magnitude of the forces imposed upon the armature magnet or magnets. If the distance between the armature magnets and the stator magnets is reduced the forces imposed upon the armature magnets by the stator magnets are increased, and the resultant force **8** vector tending to displace the armature magnets in their path of movement increases. However, the decreasing of the spacing between the armature and stator magnets creates a "pulsation" in the movement of the armature magnets which is objectionable, but can be, to some extent, minimised by using a plurality of armature magnets. Increasing the distance between the armature and stator magnets reduces the pulsation tendency of the armature magnet, but also reduces the magnitude of the magnetic forces imposed upon the armature magnets. Thus, the most effective spacing between the armature and stator magnets is that spacing which produces the maximum force vector in the direction of armature magnet movement, with a minimum creation of objectionable pulsation.

In the disclosed embodiments the high permeability plate **20** and sleeve **56** are disclosed for concentrating the magnetic field of the stator magnets, and the armature magnets are bowed and have shaped ends for magnetic field concentration purposes. While such magnetic field concentration means result in higher forces imposed upon

the armature magnets for given magnet intensities, it is not intended that the inventive concepts be limited to the use of such magnetic field concentrating means.

As will be appreciated from the above description of the invention, the movement of the armature magnet or magnets results from the described relationship of components. The length of the armature magnets as related to the width of the stator magnets and spacing between them, the dimension of the air gap and the configuration of the magnetic field, combined, produce the desired result and motion. The inventive concepts may be practised even though these relationships may be varied within limits not yet defined and the invention is intended to encompass all dimensional relationships which achieve the desired goal of armature movement. By way of example, with respect to **Figs. to 7**, the following dimensions were used in an operating prototype:

The length of armature magnet **24** is 3.125", the stator magnets **12** are 1" wide, .25" thick and 4" long and grain oriented. The air gap between the poles of the armature magnet and the stator magnets is approximately 1.5" and the spacing between the stator magnets is approximately .5" inch.

In effect, the stator magnets define a magnetic field track of a single polarity transversely interrupted at spaced locations by the magnetic fields produced by the lines of force existing between the poles of the stator magnets and the unidirectional force exerted on the armature magnet is a result of the repulsion and attraction forces existing as the armature magnet traverses this magnetic field track.

It is to be understood that the inventive concept embraces an arrangement wherein the armature magnet component is stationary and the stator assembly is supported for movement and constitutes the moving component, and other variations of the inventive concept will be apparent to those skilled in the art without departing from the scope thereof. As used herein the term "track" is intended to include both linear and circular arrangements of the static magnets, and the "direction" or "length" of the track is that direction parallel or concentric to the intended direction of armature magnet movement.

CLAIMS

1. A permanent magnet motor comprising, in combination, a stator track defining a track direction and having first and second sides and composed of a plurality of track permanent magnets each having first and second poles of opposite polarity, said magnets being disposed in side-by-side relationship having a spacing between adjacent magnets and like poles defining said track sides, an elongated armature permanent magnet located on one of said track sides for relative movement thereto and in spaced relationship to said track side wherein an air gap exists between said armature magnet and said track magnets, said armature magnet having first and second poles of opposite polarity located at the opposite ends of said armature magnet deeming the length thereof, the length of said armature magnet being disposed in a direction in general alignment with the direction of said track, the spacing of said armature magnet poles from said track associated side and the length of said armature magnet as related to the width and spacing of said track magnets in the direction of said track being such as to impose a continuous force on said armature magnet in said general direction of said track.
2. In a permanent magnet motor as in claim 1 wherein the spacing between said poles of said armature and the adjacent stator track side are substantially equal.
3. In a permanent magnet motor as in claim 1 wherein the spacing between adjacent track magnets varies.
4. In a permanent magnet motor as in claim 1 wherein a plurality of armature magnets are disposed on a common side of said stator track, said armature magnets being mechanically interconnected.
5. In a permanent magnet motor as in claim 4 wherein said armature magnets are staggered with respect to each other in the direction of said track.
6. In a permanent magnet motor as in claim 1 wherein magnetic field concentrating means are associated with said track magnets.
7. In a permanent magnet motor as in claim 6 wherein said field concentrating means comprises a sheet of magnetic material of high field permeability engaging side and pole of said track opposite to that side and pole disposed toward said armature magnet.
8. In a permanent magnet as in claim 1 wherein said armature magnet is of an arcuate configuration in its longitudinal direction bowed toward said track, said armature magnet having ends shaped to concentrate the magnetic field at said ends.

9. In a permanent magnet motor as in claim 1 wherein said stator track is of a generally linear configuration, and means supporting said armature magnet relative to said track for generally linear movement of said armature magnet.
10. In a permanent magnet motor as in claim 1 wherein said stator track magnets define a circle having an axis, an armature rotatably mounted with respect to said track and concentric and coaxial thereto, said armature magnet being mounted upon said armature.
11. In a permanent magnet motor as in claim 10, means axially adjusting said armature relative to said track whereby the axial relationship of said armature magnet and said stator magnets may be varied to adjust the rate of rotation of said armature.
12. In a permanent magnet motor as in claim 10 wherein a plurality of armature magnets are mounted on said armature.
13. In a permanent magnet motor as in claim 12 wherein said armature magnets are circumferentially non-uniformly spaced on said armature.
14. A permanent magnet motor comprising, in combination, a stator comprising a plurality of circumferentially spaced stator permanent magnets having poles of opposite polarity, said magnets being arranged to substantially define a circle having an axis, the poles of said magnets facing in a radial direction with respect to said axis and poles of the same polarity facing away from said axis and the poles of opposite polarity facing toward said axis, an armature mounted for rotation about said axis and disposed adjacent said stator, at least one armature permanent magnet having poles of opposite polarity mounted on said armature and in radial spaced relationship to said circle of stator magnets, said armature magnet poles extending in the circumferential direction of armature rotation, the spacing of said armature magnet poles from said stator magnets and the circumferential length of said armature magnet and the spacing of said stator magnets being such as to impose a continuing circumferential force on said armature magnet to rotate said armature.
15. In a permanent magnet motor as in claim 14 wherein a plurality of armature magnets are mounted upon said armature.
16. In a permanent magnet motor as in claim 14 wherein said armature magnets are asymmetrically circumferentially spaced on said armature.
17. In a permanent magnet motor as in claim 14 wherein the poles of said armature magnet are shaped to concentrate the magnetic field thereof.
18. In a permanent magnet motor as in claim 14, magnetic field concentrating means associated with said stator magnets concentrating the magnetic fields thereof at the spacings between adjacent stator magnets.
19. In a permanent magnet motor as in claim 18 wherein said magnet field concentrating means comprises an annular ring of high magnetic field permeability material concentric with said axis and in substantial engagement with poles of like polarity of said stator magnets.
20. In a permanent magnet motor as in claim 14 wherein said armature magnet is of an arcuate bowed configuration in the direction of said poles thereof defining a concave side and a convex side, said concave side being disposed toward said axis, and said poles of said armature magnet being shaped to concentrate the magnetic field between said poles thereof.
21. In a permanent magnet motor as in claim 14, means for axially displacing said stator and armature relative to each other to adjust the axial alignment of said stator and armature magnets.
22. The method of producing a unidirectional motive force by permanent magnets using a plurality of spaced stator permanent magnets having opposite polarity poles defining a track having a predetermined direction, and an armature magnet having a length defined by poles of opposite polarity movably mounted for movement relative to the track in the direction thereof, and of a predetermined length determined by the width and dimensions of said stator magnets comprising forming a magnetic field track by said stator magnets having a magnetic field of common polarity interrupted at spaced locations in a direction transverse to the direction of said magnetic field track by magnetic fields created by magnetic lines of force existing between the poles of the stator magnets and positioning the armature magnet in spaced relation to said magnetic field track longitudinally related to the direction of the magnetic field track such a distance that the repulsion and attraction forces imposed on the armature magnet by said magnetic field track imposes a continuing unidirectional force on the armature magnet in the direction of the magnetic field track.

23. The method of producing a unidirectional motive force as in claim 22 including concentrating the magnetic fields created by magnetic lines of force between the poles of the stator magnets.
24. The method of producing a unidirectional motive force as in claim 22 including concentrating the magnetic field existing between the poles of the armature magnet.
25. The method of producing a unidirectional motive force as in claim 22 including concentrating the magnetic fields created by magnetic lines of force between the poles of the stator magnets and concentrating the 12 magnetic field existing between the poles of the armature magnet.
26. The method of producing a motive force by permanent magnets wherein the unpaired electron spinning particles existing within a permanent magnet are utilised for producing a motive force comprising forming a stator magnetic field track by means of at least one permanent magnet, producing an armature magnetic field by means of a permanent magnet and shaping and locating said magnetic fields in such a manner as to produce relative continuous unidirectional motion between said stator and armature field producing magnets.
27. The method of producing a motive force by permanent magnets as in claim 26 wherein said stator magnetic field is substantially of a single polarity.
28. The method of producing a motive force by permanent magnets as in claim 26 including concentrating the magnetic field of said stator field track and armature magnetic field.

CAROUSEL ELECTRIC GENERATOR

This is a reworded excerpt from this patent which shows a compact, self-powered, combined permanent magnet motor and electrical generator. There is a little extra information at the end of this document.

ABSTRACT

A permanent magnet generator or motor having stationary coils positioned in a circle, a rotor on which are mounted permanent magnets grouped in sectors and positioned to move adjacent to the coils, and a carousel carrying corresponding groups of permanent magnets through the centres of the coils, the carousel moves with the rotor by virtue of its being magnetically coupled to it.

BACKGROUND OF THE INVENTION

There are numerous applications for small electric generators in ratings of a few kilowatts or less. Examples include electric power sources for emergency lighting in commercial and residential buildings, power sources for remote locations such as mountain cabins, and portable power sources for motor homes, pleasure boats, etc.

In all of these applications, system reliability is a primary concern. Because the power system is likely to sit idle for long periods of time without the benefit of periodic maintenance, and because the owner-operator is often inexperienced in the maintenance and operation of such equipment, the desired level of reliability can only be achieved through system simplicity and the elimination of such components as batteries or other secondary power sources which are commonly employed for generator field excitation.

Another important feature for such generating equipment is miniaturisation particularly in the case of portable equipment. It is important to be able to produce the required level of power in a relatively small generator.

Both of these requirements are addressed in the present invention through a novel adaptation of the permanent magnet generator or magneto in a design that lends itself to high frequency operation as a means for maximising power output per unit volume.

DESCRIPTION OF THE PRIOR ART

Permanent magnet generators or magnetos have been employed widely for many years. Early applications of such generators include the supply of electric current for spark plugs in automobiles and aeroplanes. Early telephones used magnetos to obtain electrical energy for ringing. The Model T Ford automobile also used magnetos to power its electric lights.

The present invention differs from prior art magnetos in terms of its novel physical structure in which a multiplicity of permanent magnets and electrical windings are arranged in a fashion which permits high-speed/high-frequency operation as a means for meeting the miniaturisation requirement. In addition, the design is enhanced through the

use of a rotating carousel which carries a multiplicity of field source magnets through the centres of the stationary electric windings in which the generated voltage is thereby induced.

SUMMARY OF THE INVENTION

In accordance with the invention claimed, an improved permanent magnet electric generator is provided with a capability for delivering a relatively high level of output power from a small and compact structure. The incorporation of a rotating carousel for the transport of the primary field magnets through the electrical windings in which induction occurs enhances field strength in the locations critical to generation.

It is, therefore, one object of this invention to provide an improved permanent magnet generator or magneto for the generation of electrical power. Another object of this invention is to provide in such a generator a relatively high level of electrical power from a small and compact structure. A further object of this invention is to achieve such a high level of electrical power by virtue of the high rotational speed and high frequency operation of which the generator of the invention is capable.

A further object of this invention is to provide such a high frequency capability through the use of a novel field structure in which the primary permanent magnets are carried through the centres of the induction windings of the generator by a rotating carousel.

A still further object of this invention is to provide a means for driving the rotating carousel without the aid of mechanical coupling but rather by virtue of magnetic coupling between other mechanically driven magnets and those mounted on the carousel.

A still further object of this invention is to provide an enhanced capability for high speed/high frequency operation through the use of an air bearing as a support for the rotating carousel.

Yet another object of this invention is to provide in such an improved generator a sufficiently high magnetic field density in the locations critical to voltage generation without resort to the use of laminations or other media to channel the magnetic field.

Further objects and advantages of the invention will become apparent as the following description proceeds and the features of novelty which characterise the invention will be pointed out with particularity in the claims annexed to and forming a part of this specification.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention may be more readily described by reference to the accompanying drawings, in which:

Fig.1 is a simplified perspective view of the carousel electric generator of the invention;

Fig.2 is a cross-sectional view of **Fig.1** taken along line 2--2;

Fig.3 is a cross-sectional view of the generator of **Fig.1** and **Fig.2** taken along line 3--3 of **Fig.2**;

FIG. 4

Fig.4 is a cross-sectional view of **Fig.3** taken along line 4--4;

Fig.5 is a partial perspective view showing the orientation of a group of permanent magnets within a twenty degree sector of the generator of the invention as viewed in the direction of arrow **5** of **Fig.3**;

Fig.6 is an illustration of the physical arrangement of electrical windings and permanent magnets within the generator of the invention as viewed in the direction of arrow **6** in **Fig.1**;

FIG. 7

Fig.7 is a wave form showing flux linkages for a given winding as a function of rotational position of the winding relative to the permanent magnets;

FIG. 8

Fig.8 is a schematic diagram showing the proper connection of the generator windings for a high current low voltage configuration of the generator;

FIG. 9

Fig.9 is a schematic diagram showing a series connection of generator coils for a low current, high voltage configuration;

FIG. 10

Fig.10 is a schematic diagram showing a series/parallel connection of generator windings for intermediate current and voltage operation;

Fig.11 is a perspective presentation of a modified carousel magnet configuration employed in a second embodiment of the invention;

Fig.12A and **Fig.12B** show upper and lower views of the carousel magnets of **Fig.11**;

Fig.13 is a cross-sectional view of the modified magnet configuration of **Fig.11** taken along line 13--13 with other features of the modified carousel structure also shown;

FIG. 14

Fig.14 is a modification of the carousel structure shown in Figs. 1-13 wherein a fourth carousel magnet is positioned at each station; and

FIG. 15

Fig.15 illustrates the use of the claimed device as a pulsed direct current power source.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring more particularly to the drawings by characters of reference, **Fig.1** shows the external proportions of a carousel electric generator **10** of the invention. As shown in **Fig.1**, generator **10** is enclosed by a housing **11** with mounting feet **12** suitable for securing the generator to a flat surface **13**. The surface **13** is preferably horizontal, as shown in **Fig.1**.

Housing **11** has the proportions of a short cylinder. A drive shaft **14** extends axially from housing **11** through a bearing **15**. The electrical output of the generator is brought out through a cable **16**.

The cross-sectional view of **Fig.2** shows the active elements incorporated in one twenty degree sector of the stator and in one twenty degree sector of the rotor.

In the first implementation of the invention, there are eighteen identical stator sectors, each incorporating a winding or coil **17** wound about a rectangular coil frame or bobbin. Coil **17** is held by a stator frame **18** which may also serve as an outer wall of frame **11**.

The rotor is also divided into eighteen sectors, nine of which incorporate three permanent magnets each, including an inboard rotor magnet **19**, an upper rotor magnet **21** and a lower rotor magnet **22**. All three of these magnets have their south poles facing coil **17**, and all three are mounted directly on rotor frame **23** which is secured directly to drive shaft **14**.

The other nine sectors of the rotor are empty, i.e. they are not populated with magnets. The unpopulated sectors are alternated with the populated sectors so that adjacent populated sectors are separated by an unpopulated sector as shown in **Fig.3** and **Fig.6**.

With reference again to **Fig.2**, generator **10** also incorporates a carousel **24**. The carousel comprises nine pairs of carousel magnets **25** clamped between upper and lower retainer rings **26** and **27**, respectively. The lower retainer ring **27** rests inside an air bearing channel **28** which is secured to stator **18** inside the bobbin of coil **17**. Air passages (not shown) admit air into the space between the lower surface of ring **27** and the upper or inside

surface of channel **28**. This arrangement comprises an air bearing which permits carousel **24** to rotate freely within the coils **17** about rotational axis **29** of rotor frame **23**.

Carousel **24** is also divided into **18** twenty-degree sectors, including nine populated sectors interspersed with nine unpopulated sectors in an alternating sequence. Each of the nine populated sectors incorporates a pair of carousel magnets as described in the preceding paragraph.

The geometrical relationship between the rotor magnets, the carousel magnets and the coils, is further clarified by **Fig.3**, **Fig.4** and **Fig.5**. In each of the three figures, the centre of each populated rotor sector is shown aligned with the centre of a coil **17**. Each populated carousel sector, which is magnetically locked into position with a populated rotor sector, is thus also aligned with a coil **17**.

In an early implementation of the invention, the dimensions and spacings of the rotor magnets **19**, **21** and **22** and carousel magnets, **25A** and **25B** of carousel magnet pairs **25** were as shown in **Fig.5**. Each of the rotor magnets **19**, **21** and **22** measured one inch by two inches by one-half inch with north and south poles at opposite one-inch by two-inch faces. Each of the carousel magnets **25A** and **25B** measured two inches by two inches by one-half inch with north and south poles at opposite two-inch by two-inch faces. The magnets were obtained from Magnet Sales and Manufacturing, Culver City, Calif. The carousel magnets were part No.35NE2812832; the rotor magnets were custom parts of equivalent strength (MMF) but half the cross section of the carousel magnets.

Coil supports and other stationary members located within magnetic field patterns are fabricated from Delrin or Teflon plastic or equivalent materials. The use of aluminium or other metals introduce eddy current losses and in some cases excessive friction.

As shown in **Fig.5**, carousel magnets **25A** and **25B** stand on edge, parallel with each other, their north poles facing each other, and spaced one inch apart. When viewed from directly above the carousel magnets, the space between the two magnets **25A** and **25B** appears as a one-inch by two-inch rectangle. When the carousel magnet pair **25** is perfectly locked into position magnetically, upper rotor magnet **21** is directly above this one-inch by two-inch rectangle, lower rotor magnet **22** is directly below it, and their one-inch by two-inch faces are directly aligned with it, the south poles of the two magnets **21** and **22** facing each other.

In like manner, when viewed from the axis of rotation of generator **10**, the space between carousel magnets **25A** and **25B** again appears as a one-inch by two-inch rectangle, and this rectangle is aligned with the one-inch by two-inch face of magnet **19**, the south pole of magnet **19** facing the carousel magnet pair **25**.

Rotor magnets **19**, **21** and **22** are positioned as near as possible to carousel magnets **25A** and **25B** while still allowing passage for coil **17** over and around the carousel magnets and through the space between the carousel magnets and the rotor magnets.

In an electric generator, the voltage induced in the generator windings is proportional to the product of the number of turns in the winding and the rate of change of flux linkages that is produced as the winding is rotated through

the magnetic field. An examination of magnetic field patterns is therefore essential to an understanding of generator operation.

In generator **10**, magnetic flux emanating from the north poles of carousel magnets **25A** and **25B** pass through the rotor magnets and then return to the south poles of the carousel magnets. The total flux field is thus driven by the combined MMF (magnetomotive force) of the carousel and field magnets while the flux patterns are determined by the orientation of the rotor and carousel magnets.

The flux pattern between carousel magnets **25A** and **25B** and the upper and lower rotor magnets **21** and **22** is illustrated in **Fig.4**. Magnetic flux lines **31** from the north pole of carousel magnet **25A** extend to the south pole of upper rotor magnet **21**, pass through magnet **21** and return as lines **31'** to the south pole of magnet **25A**. Lines **33**, also from the north pole of magnet **25A** extend to the south pole of lower rotor magnet **22**, pass through magnet **22** and return to the south pole of magnet **25A** as lines **33'**. Similarly, lines **32** and **34** from the north pole of magnet **25B** pass through magnets **21** and **22**, respectively, and return as lines **32'** and **34'** to the south pole of magnet **25B**. Flux linkages produced in coil **17** by lines emanating from carousel magnet **25A** are of opposite sense from those emanating from carousel magnet **25B**. Because induced voltage is a function of the rate of change in net flux linkages, it is important to recognise this difference in sense.

Fig.6 shows a similar flux pattern for flux between carousel magnets **25A** and **25B** and inboard rotor magnet **19**. Again the lines emanating from carousel magnet **25A** and passing through rotor magnet **19** produce flux linkages in coil **17** that are opposite in sense from those produced by lines from magnet **25B**.

The arrangement of the carousel magnets with the north poles facing each other tends to confine and channel the flux into the desired path. This arrangement replaces the function of magnetic yokes or laminations of more conventional generators.

The flux linkages produced by magnets **25A** and **25B** are opposite in sense regardless of the rotational position of coil **17** including the case where coil **17** is aligned with the carousel and rotor magnets as well as for the same coils when they are aligned with an unpopulated rotor sector.

Taking into account the flux patterns of **Fig.4** and **Fig.6** and recognising the opposing sense conditions just described, net flux linkages for a given coil **17** are deduced as shown in **Fig.7**.

In **Fig.7**, net flux linkages (coil-turns x lines) are plotted as a function of coil position in degrees. Coil position is here defined as the position of the centreline **35** of coil **17** relative to the angular scale shown in degrees in **Fig.6**. (Note that the coil is stationary and the scale is fixed to the rotor. As the rotor turns in a clockwise direction, the relative position of coil **17** progresses from zero to ten to twenty degrees etc.).

At a relative coil position of ten degrees, the coil is centred between magnets **25A** and **25B**. Assuming symmetrical flux patterns for the two magnets, the flux linkages from one magnet exactly cancel the flux linkages from the other so that net flux linkages are zero. As the relative coil position moves to the right, linkages from magnet **25A** decrease and those from magnet **25B** increase so that net flux linkages build up from zero and passes through a maximum negative value at some point between ten and twenty degrees. After reaching the negative maximum, flux linkages decrease, passing through zero at 30 degrees (where coil **17** is at the centre of an unpopulated rotor sector) and then rising to a positive maximum at some point just beyond 60 degrees. This cyclic variation repeats as the coil is subjected successively to fields from populated and unpopulated rotor sectors.

As the rotor is driven rotationally, net flux linkages for all eighteen coils are altered at a rate that is determined by the flux pattern just described in combination with the rotational velocity of the rotor. Instantaneous voltage

induced in coil 17 is a function of the slope of the curve shown in **Fig.7** and rotor velocity, and voltage polarity changes as the slope of the curve alternates between positive and negative.

It is important to note here that a coil positioned at ten degrees is exposed to a negative slope while the adjacent coil is exposed to a positive slope. The polarities of the voltages induced in the two adjacent coils are therefore opposite. For series or parallel connections of odd and even-numbered coils, this polarity discrepancy can be corrected by installing the odd and even numbered coils oppositely (odds rotated end for end relative to evens) or by reversing start and finish connections of odd relative to even numbered coils. Either of these measures will render all coil voltages additive as needed for series or parallel connections. Unless the field patterns for populated and unpopulated sectors are very nearly symmetrical, however, the voltages induced in odd and even numbered coils will have different waveforms. This difference will not be corrected by the coil reversals or reverse connections discussed in the previous paragraph. Unless the voltage waveforms are very nearly the same, circulating currents will flow between even and odd-numbered coils. These circulating currents will reduce generator efficiency.

FIG.8

To prevent such circulating currents and the attendant loss in operating efficiency for non symmetrical field patterns and unmatched voltage waveforms, the series-parallel connections of **Fig.8** may be employed in a high-current, low-voltage configuration of the generator. If the eighteen coils are numbered in sequence from one to eighteen according to position about the stator, all even-numbered coils are connected in parallel, all odd-numbered coils are connected in parallel, and the two parallel coil groups are connected in series as shown with reversed polarity for one group so that voltages will be in phase relative to output cable 16.

FIG.9

For a low-current, high voltage configuration, the series connection of all coils may be employed as shown in **Fig.9**. In this case, it is only necessary to correct the polarity difference between even and odd numbered coils. As mentioned earlier, this can be accomplished by means of opposite start and finish connections for odd and even coils or by installing alternate coils reversed, end for end.

FIG.10

For intermediate current and voltage configurations, various series-parallel connections may be employed. **Fig.10**, for example, shows three groups of six coils each connected in series. Circulating currents will be avoided so long as even-numbered coils are not connected in parallel with odd-numbered coils. Parallel connection of

series-connected odd/even pairs as shown is permissible because the waveforms of the series pairs should be very neatly matched.

In another embodiment of the invention, the two large (two-inch by two-inch) carousel magnets are replaced by three smaller magnets as shown in **Fig. 11**, **Fig. 12** and **Fig. 13**. The three carousel magnets comprise an inboard carousel magnet **39**, an upper carousel magnet **41** and a lower carousel magnet **42** arranged in a U-shaped configuration that matches the U-shaped configuration of the rotor magnets **19**, **21** and **22**. As in the case of the first embodiment, the rotor and carousel magnets are present only in alternate sectors of the generator.

The ends of the carousel magnets are bevelled to permit a more compact arrangement of the three magnets. As shown in **Fig. 12**, each magnet measures one inch by two inches by one half inch thick. The south pole occupies the bevelled one-inch by two-inch face and the north pole is at the opposite face.

The modified carousel structure **24'** as shown in **Fig.13** comprises an upper carousel bearing plate **43**, a lower carousel bearing plate **44**, an outer cylindrical wall **45** and an inner cylindrical wall **46**. The upper and lower bearing plates **43** and **44** mate with the upper and lower bearing members **47** and **48**, respectively, which are stationary and secured inside the forms of the coils **17**. Bearing plates **43** and **44** are shaped to provide air channels **49** which serve as air bearings for rotational support of the carousel **24'**. The bearing plates are also slotted to receive the upper and lower edges **51** of cylindrical walls **45** and **46**.

The modified carousel structure **24'** offers a number of advantages over the first embodiment. The matched magnet configuration of the carousel and the rotor provides tighter and more secure coupling between the carousel and the rotor. The smaller carousel magnets also provide a significant reduction in carousel weight. This was found beneficial relative to the smooth and efficient rotational support of the carousel.

FIG. 14

The modification of the carousel structure as described in the foregoing paragraphs can be taken one step further with the addition of a fourth carousel magnet **52** at each station as shown in **Fig.14**. The four carousel magnets **39**, **41**, **42** and **52** now form a square frame with each of the magnet faces (north poles) facing a corresponding inside face of the coil **17**. Carousel magnets for this modification may again be as shown in **Fig.12**. An additional rotor magnet **53** may also be added as shown, in alignment with carousel magnet **52**. These additional modifications further enhance the field pattern and the degree of coupling between the rotor and the carousel.

The carousel electric generator of the invention is particularly well suited to high speed, high frequency operation where the high speed compensates for lower flux densities than might be achieved with a magnetic medium for routing the field through the generator coils. For many applications, such as emergency lighting, the high frequency is also advantageous. Fluorescent lighting, for example, is more efficient in terms of lumens per watt and the ballasts are smaller at high frequencies.

While the present invention has been directed toward the provision of a compact generator for specialised generator applications, it is also possible to operate the device as a motor by applying an appropriate alternating voltage source to cable **16** and coupling drive shaft **14** to a load.

FIG. 15

It is also possible to operate the device of the invention as a motor using a pulsed direct-current power source. A control system **55** for providing such operation is illustrated in **Fig. 15**. Incorporated in the control system **55** are a rotor position sensor **S**, a programmable logic controller **56**, a power control circuit **57** and a potentiometer **P**.

Based on signals received from sensor **S**, controller **56** determines the appropriate timing for coil excitation to assure maximum torque and smooth operation. This entails the determination of the optimum positions of the rotor and the carousel at the initiation and at the termination of coil excitation. For smooth operation and maximum torque, the force developed by the interacting fields of the magnets and the excited coils should be unidirectional to the maximum possible extent.

Typically, the coil is excited for only 17.5 degrees or less during each 40 degrees of rotor rotation.

The output signal **58** of controller **56** is a binary signal (high or low) that is interpreted as an ON and OFF command for coil excitation.

The power control circuit incorporates a solid state switch in the form of a power transistor or a MOSFET. It responds to the control signal **58** by turning the solid state switch ON and OFF to initiate and terminate coil excitation. Instantaneous voltage amplitude supplied to the coils during excitation is controlled by means of potentiometer **P**. Motor speed and torque are thus responsive to potentiometer adjustments.

The device is also adaptable for operation as a motor using a commutator and brushes for control of coil excitation. In this case, the commutator and brushes replace the programmable logic controller and the power control circuit as the means for providing pulsed DC excitation. This approach is less flexible but perhaps more efficient than the programmable control system described earlier.

It will now be recognised that a novel and useful generator has been provided in accordance with the stated objects of the invention, and while but a few embodiments of the invention have been illustrated and described it will be apparent to those skilled in the art that various changes and modifications may be made without departing from the spirit of the invention or from the scope of the appended claims.

Notes:

I found it a little difficult to visualise the carousel part, so the following may be helpful for some people. The "carousel" is formed from two circular plastic channels like this:

These channels are placed, one below and one above, nine pairs of carousel magnets (coloured blue in some of the patent diagrams shown above. Each carousel magnet sits in the lower channel:

And these magnets are secured as a unit by an identical plastic channel inverted and placed on top of the magnet set:

And this ring assembly of magnets spins inside the wire coils used to generate the electrical output. The ring spins inside the coils because the nine pairs of magnets in the ring, lock in place opposite the matching nine pairs of magnets in the rotor and the magnetic force and rotor rotation causes the ring to spin inside the coils.

OPTICAL GENERATOR OF AN ELECTROSTATIC FIELD HAVING LONGITUDINAL OSCILLATION AT LIGHT FREQUENCIES FOR USE IN AN ELECTRICAL CIRCUIT

Please note that this is a re-worded excerpt from this patent. It describes a gas-filled tube which allows many standard 40-watt fluorescent tubes to be powered using less than 1-watt of power each.

ABSTRACT

An Optical generator of an electrostatic field at light frequencies for use in an electrical circuit, the generator having a pair of spaced-apart electrodes in a gas-filled tube of quartz glass or similar material with at least one capacitor cap or plate adjacent to one electrode and a dielectric filled container enclosing the tube, the generator substantially increasing the electrical efficiency of the electrical circuit.

BACKGROUND OF THE INVENTION

This invention relates to improved electrical circuits, and more particularly to circuits utilising an optical generator of an electrostatic field at light frequencies.

The measure of the efficiency of an electrical circuit may broadly be defined as the ratio of the output energy in the desired form (such as light in a lighting circuit) to the input electrical energy. Up to now, the efficiency of many circuits has not been very high. For example, in a lighting circuit using 40 watt fluorescent lamps, only about 8.8 watts of the input energy per lamp is actually converted to visible light, thus representing an efficiency of only about 22%. The remaining 31.2 watts is dissipated primarily in the form of heat.

It has been suggested that with lighting circuits having fluorescent lamps, increasing the frequency of the applied current will raise the overall circuit efficiency. While at an operating frequency of 60 Hz, the efficiency is 22%, if the frequency is raised to 1 Mhz, the circuit efficiency would only rise to some 25.5%. Also, if the input frequency were raised to 10 Ghz, the overall circuit efficiency would only be 35%.

SUMMARY OF THE PRESENT INVENTION

The present invention utilises an optical electrostatic generator which is effective for producing high frequencies in the visible light range of about 10^{14} to 10^{23} Hz. The operation and theory of the optical electrostatic generator has been described and discussed in my co-pending application serial No. 5,248, filed on 23rd January 1970. As stated in my co-pending application, the present optical electrostatic generator does not perform in accordance with the accepted norms and standards of ordinary electromagnetic frequencies.

The optical electrostatic generator as utilised in the present invention can generate a wide range of frequencies between several Hertz and those in the light frequency. Accordingly, it is an object of the present invention to provide improved electrical energy circuits utilising my optical electrostatic generator, whereby the output energy in the desired form will be substantially more efficient than possible to date, using standard circuit techniques and equipment. It is a further object of the present invention to provide such a circuit for use in fluorescent lighting or other lighting circuits. It is also an object of the present invention to provide a circuit with may be used in conjunction with electrostatic precipitators for dust and particle collection and removal, as well as many other purposes.

DESCRIPTION OF THE DRAWINGS

Fig.1 is a schematic layout showing an optical electrostatic generator of the present invention, utilised in a lighting circuit for fluorescent lamps:

Fig.2 is a schematic layout of a high-voltage circuit incorporating an optical electrostatic generator:

Fig.2A is a sectional view through a portion of the generator and

Fig.3 is a schematic sectional view showing an optical electrostatic generator in accordance with the present invention, particularly for use in alternating current circuits, although it may also be used in direct current circuits:

DESCRIPTION OF THE ILLUSTRATED EMBODIMENTS

Referring to the drawings and to **Fig.1** in particular, a low voltage circuit utilising an optical electrostatic generator is shown. As shown in **Fig.1**, a source of alternating current electrical energy **10**, is connected to a lighting circuit. Connected to one tap of the power source **10** is a rectifier **12** for utilisation when direct current is required. The illustrated circuit is provided with a switch **14** which may be opened or closed depending on whether AC or DC power is used. Switch **14** is opened and a switch **16** is closed when AC is used. With switch **14** closed and switch **16** open, the circuit operates as a DC circuit.

Extending from switches **14** and **16** is conductor **18** which is connected to an optical electrostatic generator **20**. Conductor **18** is passed through an insulator **22** and connected to an electrode **24**. Spaced from electrode **24** is a second electrode **25**. Enclosing electrodes **24** and **25**, which preferably are made of tungsten or similar material, is a quartz glass tube **26** which is filled with an ionisable gas **28** such as xenon or any other suitable ionisable gas such as argon, krypton, neon, nitrogen or hydrogen, as well as the vapour of metals such as mercury or sodium.

Surrounding each end of tube **26** and adjacent to electrodes **24** and **25**, are capacitor plates **30** and **32** in the form of caps. A conductor is connected to electrode **25** and passed through a second insulator **34**. Surrounding the tube, electrodes and capacitor caps is a metal envelope in the form of a thin sheet of copper or other metal such as aluminium. Envelope **36** is spaced from the conductors leading into and out of the generator by means of insulators **22** and **34**. Envelope **36** is filled with a dielectric material such as transformer oil, highly purified distilled water, nitro-benzene or any other suitable liquid dielectric. In addition, the dielectric may be a solid such as ceramic material with relatively small molecules.

A conductor **40** is connected to electrode **25**, passed through insulator **34** and then connected to a series of fluorescent lamps **42** which are connected in series. It is the lamps **42** which will be the measure of the efficiency of the circuit containing the optical electrostatic generator **20**. A conductor **44** completes the circuit from the fluorescent lamps to the tap of the source of electrical energy **10**. In addition, the circuit is connected to a ground **46** by another conductor **48**. Envelope **36** is also grounded by lead **50** and in the illustrated diagram, lead **50** is connected to the conductor **44**.

The capacitor caps or plates **30** and **32**, form a relative capacitor with the discharge tube. When a high voltage is applied to the electrode of the discharge tube, the ions of gas are excited and brought to a higher potential than their environment, i.e. the envelope and the dielectric surrounding it. At this point, the ionised gas in effect becomes one plate of a relative capacitor in co-operation with the capacitor caps or plates **30** and **32**.

When this relative capacitor is discharged, the electric current does not decrease as would normally be expected. Instead, it remains substantially constant due to the relationship between the relative capacitor and an absolute capacitor which is formed between the ionised gas and the spaced metal envelope **36**. An oscillation effect occurs in the relative capacitor, but the electrical condition in the absolute capacitor remains substantially constant.

As also described in the co-pending application serial No. 5,248, there is an oscillation effect between the ionised gas in the discharge lamp and the metallic envelope **36** will be present if the capacitor caps are eliminated, but the efficiency of the electrostatic generator will be substantially decreased.

The face of the electrode can be any desired shape. However, a conical point of 60° has been found to be satisfactory and it is believed to have an influence on the efficiency of the generator.

In addition, the type of gas selected for use in tube **26**, as well as the pressure of the gas in the tube, also affect the efficiency of the generator, and in turn, the efficiency of the electrical circuit.

To demonstrate the increased efficiency of an electrical circuit utilising the optical electrostatic generator of the present invention as well as the relationship between gas pressure and electrical efficiency, a circuit similar to that shown in **Fig.1** may be used with 100 standard 40 watt, cool-white fluorescent lamps connected in series. The optical electrostatic generator includes a quartz glass tube filled with xenon, with a series of different tubes being used because of the different gas pressures being tested.

Table 1 shows the data to be obtained relating to the optical electrostatic generator. **Table 2** shows the lamp performance and efficiency for each of the tests shown in **Table 1**. The following is a description of the data in each of the columns of **Tables 1 and 2**.

Column	Description
B	Gas used in discharge tube
C	Gas pressure in tube (in torrs)
D	Field strength across the tube (measured in volts per cm. of length between the electrodes)
E	Current density (measured in microamps per sq. mm. of tube cross-sectional area)
F	Current (measured in amps)
G	Power across the tube (calculated in watts per cm. of length between the electrodes)
H	Voltage per lamp (measured in volts)
K	Current (measured in amps)
L	Resistance (calculated in ohms)
M	Input power per lamp (calculated in watts)
N	Light output (measured in lumens)

The design of a tube construction for use in the optical electrostatic generator of the type used in **Fig.1**, may be accomplished by considering the radius of the tube, the length between the electrodes in the tube and the power across the tube.

If **R** is the minimum inside radius of the tube in centimetres, **L** the minimum length in centimetres between the electrodes, and **W** the power in watts across the lamp, the following formula can be obtained from **Table 1**:

$$R = (\text{Current [A]} / \text{Current Density [A/sq.mm]}) / \pi$$

$$L = 8R$$

$$W = L[V/cm] \times A$$

For example, for Test No. 18 in Table 1:

The current is 0.1818 A,

The current density 0.000353 A/sq.mm and

The Voltage Distribution is 122.8 V/cm; therefore

$$R = (0.1818 / 0.000353)^2 / 3.14 = 12.80 \text{ mm.}$$

$$L = 8 \times R = 8 \times 12.8 = 102.4 \text{ mm (10.2 cm.)}$$

$$W = 10.2 \times 122.8 \times 0.1818 = 227.7 \text{ VA or 227.7 watts}$$

The percent efficiency of operation of the fluorescent lamps in Test No. 18 can be calculated from the following equation:

$$\% \text{ Efficiency} = (\text{Output Energy/Input energy}) \times 100$$

Across a single fluorescent lamp, the voltage is 60 volts and the current is 0.1818 amps therefore the input energy to the lamp **42** is 10.90 Watts. The output of the fluorescent lamp is 3,200 lumens which represents 8.8 Watts power of light energy. Thus, the one fluorescent lamp is operating at 80.7% efficiency under these conditions.

However, when the optical generator is the same as described for Test No. 18 and there are 100 fluorescent lamps in series in the circuit, the total power input is 227.7 watts for the optical generator and 1,090 watts for 100 fluorescent lamps, or a total of 1,318 watts. The total power input normally required to operate the 100 fluorescent lamps in a normal circuit would be $100 \times 40 = 4,000$ watts. So by using the optical generator in the circuit, about 2,680 watts of energy is saved.

Table 1 is an example of the functioning of this invention for a particular fluorescent lamp (40 watt cool white). However, similar data can be obtained for other lighting applications, by those skilled in the art.

In **Fig.2**, a circuit is shown which uses an optical electrostatic generator **20a**, similar to generator **20** of **Fig.1**. In generator **20**, only one capacitor cap **32a** is used and it is preferably of triangular cross-sectional design. In addition, the second electrode **25a** is connected directly back into the return conductor **52**, similar to the arrangement shown in my co-pending application serial No. 5,248, filed 23rd January 1970.

This arrangement is preferably for very high voltage circuits and the generator is particularly suited for DC usage.

In **Fig.2**, common elements have received the same numbers which were used in **Fig.1**.

In **Fig.3**, still another embodiment of an optical electrostatic generator **20b** is shown. This generator is particularly suited for use with AC circuits. In this embodiment, the capacitor plates **30b** and **32b** have flanges **54** and **56** which extend outwards towards the envelope **36**. While the utilisation of the optical electrostatic generator has been described in use in a fluorescent lighting circuit, it is to be understood that many other types of circuits may be used. For example, the high-voltage embodiment may be used in a variety of circuits such as flash lamps, high-speed controls, laser beams and high-energy pulses. The generator is also particularly usable in a circuit including electrostatic particle precipitation in air pollution control devices, chemical synthesis in electrical discharge systems such as ozone generators and charging means for high-voltage generators of the Van de Graff type, as well as particle accelerators. To those skilled in the art, many other uses and circuits will be apparent.

APPARATUS FOR PRODUCING AN ELECTRIC CURRENT

This patent shows the details of a lightweight device which can produce electricity using a self-powered electromagnet and chemical salts. The working life of the device before needing a recharge is estimated at some seventy years. The operation is controlled by a transmitter which bombards the chemical sample with 300 MHz radio waves. This produces radioactive emissions from the chemical mixture for a period of one hour maximum, so the transmitter needs to be run for fifteen to thirty seconds once every hour. The chemical mixture is shielded by a lead screen to prevent harmful radiation reaching the user. The output from the tiny device described is estimated to be some 10 amps at 100 to 110 volts DC.

DESCRIPTION

This invention relates to a new apparatus for producing electric current the apparatus being in the form of a completely novel secondary battery. The object of this invention is to provide apparatus of the above kind which is considerably lighter in weight than, and has an infinitely greater life than a known battery or similar characteristics and which can be re-activated as and when required in a minimum of time.

According to the present invention we provide apparatus comprising a generator unit which includes a magnet, a means for suspending a chemical mixture in the magnetic field, the mixture being composed of elements whose nuclei becomes unstable as a result of bombardment by short waves so that the elements become radio-active and release electrical energy, the mixture being mounted between, and in contact with, a pair of different metals such as copper and zinc, a capacitor mounted between those metals, a terminal electrically connected to each of the metals, means for conveying the waves to the mixture and a lead shield surrounding the mixture to prevent harmful radiation from the mixture.

The mixture is preferably composed of the elements Cadmium, Phosphorus and Cobalt having Atomic Weights of 112, 31 and 59 respectively. The mixture, which may be of powdered form, is mounted in a tube of non-conducting, high heat resistivity material and is compressed between granulated zinc at one end of the tube and granulated copper at the other end, the ends of the tube being closed by brass caps and the tube being carried in a suitable cradle so that it is located between the poles of the magnet. The magnet is preferably an electro-magnet and is energised by the current produced by the unit.

The means for conveying the waves to the mixture may be a pair of antennae which are exactly similar to the antennae of the transmitter unit for producing the waves, each antenna projecting from and being secured to the brass cap at each end of the tube.

The transmitter unit which is used for activating the generator unit may be of any conventional type operating on ultra-shortwave and is preferably crystal controlled at the desired frequency.

DESCRIPTION OF THE DRAWINGS

Fig.1 is a side elevation of one form of the apparatus.

Fig.2 is a view is an end elevation

Fig.3 is a schematic circuit diagram.

In the form of our invention illustrated, the generator unit comprises a base **10** upon which the various components are mounted. This base **10**, having projecting upwards from it a pair of arms **11**, which form a cradle housing **12** for a quartz tube **13**, the cradle **12** preferably being made of spring material so that the tube **13** is firmly, yet removably held in position. The arms **11** are positioned relative to the poles **14** of an electromagnet **15** so that the tube **13** is located immediately between the poles of the magnet so as to be in the strongest magnetic field created by the electromagnet. The magnet serves to control the alpha and beta rays emitted by the cartridge when it is in operation.

The ends of the quartz tube **13** are each provided with a brass cap **16**, and these caps **16** are adapted to engage within the spring cradles **12** and the coils **17** associated with the magnet being so arranged that if the base **10** of the unit is in a horizontal plane, the poles **14** of the magnet are in a substantially vertical plane.

Also connected across the cradles is a lead capacitor **18** which may conveniently be housed in the base **10** of the unit and connected in parallel with this capacitor **18** is a suitable high frequency inductance coil **19**. The unit is provided with a lead shield **20** so as to prevent harmful radiation from the quartz tube as will be described later.

The quartz tube **13** has mounted in it, at one end, a quantity of granulated copper which is in electrical contact with the brass cap **16** at that end of the tube. Also mounted within the tube and in contact with the granulated copper is a chemical mixture which is in powdered form and which is capable of releasing electrical energy and which becomes radioactive when subjected to bombardment by ultra-short radio waves.

Mounted in the other end of the tube, and in contact with the other end of the powdered chemical mixture is a quantity of granulated zinc which is itself in contact with the brass cap on this end of the tube, the arrangement being that the chemical mixture is compressed between the granulated copper and the granulated zinc.

Projecting outwards from each brass cap **16**, and electrically connected to them, is an antenna **21**. Each antenna **21** corresponding exactly in dimension, shape and electrical characteristics to the antenna associated with a transmitter unit which is to produce the ultra shortwaves mentioned earlier.

The electromagnet **15** is conveniently carried by a centrally positioned pillar **22** which is secured to the base **10**. At the upper end of pillar **22** there is a cross-bar **23**, which has the high frequency coil **19** attached to one end of it. The other end of the cross-bar **23** is bent around into the curved shape as shown at **24** and is adapted to bear against a curved portion **25** of the base **26** of the electromagnet **15**. A suitable locking device is provided for holding the curved portions **24** and **25** in the desired angular position, so that the position of the poles **14** of the electromagnet can be adjusted about the axis of the quartz tube **13**.

The transmitter unit is of any suitable conventional type for producing ultra shortwaves and may be crystal controlled to ensure that it operates at the desired frequency with the necessity of tuning. If the transmitter is only required to operate over a short range, it may conveniently be battery powered but if it is to operate over a greater range, then it may be operated from a suitable electrical supply such as the mains. If the transmitter is to be tuned, then the tuning may be operated by a dial provided with a micrometer vernier scale so that the necessary tuning accuracy may be achieved.

The mixture which is contained within the quartz tube is composed of the elements Cadmium, Phosphorus and Cobalt, having atomic weights 112, 31 and 59 respectively. Conveniently, these elements may be present in the following compounds, and where the tube is to contain thirty milligrams of the mixture, the compounds and their proportions by weight are:

1 Part of $\text{Co}(\text{No}_3) 2 6\text{H}_2\text{O}$
2 Parts of CdCl_2
3 Parts of $3\text{Ca}(\text{Po}_3) 2 + 10\text{C}$.

The cartridge which consists of the tube **13** with the chemical mixture in it is preferably composed of a number of small cells built up in series. In other words, considering the cartridge from one end to the other, at one end and in contact with the brass cap, there would be a layer of powdered copper, then a layer of the chemical mixture, then a layer of powdered zinc, a layer of powdered copper, etc. with a layer of powdered zinc in contact with the brass cap at the other end of the cartridge. With a cartridge some forty five millimetres long and five millimetres diameter, some fourteen cells may be included.

The cradles **12** in which the brass caps **16** engage, may themselves form terminals from which the output of the unit may be taken. Alternatively, a pair of terminals **27** may be connected across the cradles **12**, these terminals **27** being themselves provided with suitable antennae **28**, which correspond exactly in dimensions, shape and electrical characteristics to the antennae associated with the transmitter, these antennae **28**, replacing the antennae **21**.

In operation with the quartz tube containing the above mixture located between the granulated copper and the granulated zinc and with the tube itself in position between the poles of the magnet, the transmitter is switched on and the ultra shortwaves coming from it are received by the antennae mounted at each end of the tube and in contact with the copper and zinc respectively, the waves being thus passed through the copper and zinc and through the mixture so that the mixture is bombarded by the short waves and the Cadmium, Phosphorus and Cobalt associated with the mixture become radioactive and release electrical energy which is transmitted to the granulated copper and granulated zinc, causing a current to flow between them in a similar manner to the current

flow produced by a thermo couple. It has been established that with a mixture having the above composition, the optimum release of energy is obtained when the transmitter is operating at a frequency of 300 MHz.

The provision of a quartz tube is necessary for the mixture evolves a considerable amount of heat while it is reacting to the bombardment of the short waves. It is found that the tube will only last for one hour and that the tube will become discharged after an hours operation, that is to say, the radioactiveness of the tube will only last for one hour and it is therefore necessary, if the unit is to be run continuously, for the transmitter to be operated for a period of some fifteen to thirty seconds duration once every hour.

With a quartz tube having an overall length of some forty five millimetres and an inside diameter of five millimetres and containing thirty milligrams of the chemical mixture, the estimated energy which will be given off from the tube for a discharge of one hour, is 10 amps at between 100 and 110 volts. To enable the tube to give off this discharge, it is only necessary to operate the transmitter at the desired frequency for a period of some fifteen to thirty seconds duration.

The current which is given off by the tube during its discharge is in the form of direct current. During the discharge from the tube, harmful radiations are emitted in the form of gamma rays, alpha rays and beta rays and it is therefore necessary to mount the unit within a lead shield to prevent the harmful radiations from affecting personnel and objects in the vicinity of the unit. The alpha and beta rays which are emitted from the cartridge when it is in operation are controlled by the magnet.

When the unit is connected up to some apparatus which is to be powered by it, it is necessary to provide suitable fuses to guard against the cartridge being short-circuited which could cause the cartridge to explode.

The estimated weight of such a unit including the necessary shielding, per kilowatt hour output, is approximately 25% of any known standard type of accumulator which is in use today and it is estimated that the life of the chemical mixture is probably in the region of seventy to eighty years when under constant use.

It will thus be seen that we have provided a novel form of apparatus for producing an electric current, which is considerably lighter than the standard type of accumulator at present known, and which has an infinitely greater life than the standard type of accumulator, and which can be recharged or reactivated as and when desired and from a remote position depending on the power output of the transmitter. Such form of battery has many applications.

NO-LOAD GENERATOR

Electrical power is frequently generated by spinning the shaft of a generator which has some arrangement of coils and magnets contained within it. The problem is that when current is drawn from the take-off coils of a typical generator, it becomes much more difficult to spin the generator shaft. The cunning design shown in this patent overcomes this problem with a simple design in which the effort required to turn the shaft is not altered by the current drawn from the generator.

ABSTRACT

A generator of the present invention is formed of ring permanent magnet trains 2 and 2' attached and fixed on to two orbits 1 and 1' about a rotational axis 3, magnetic induction primary cores 4 and 4' attached and fixed above outer peripheral surfaces of the ring permanent magnet trains 2 and 2' at a predetermined distance from the outer peripheral surfaces, magnetic induction secondary cores 5 and 5' attached and fixed on to the magnetic induction primary cores 4 and 4' and each having two coupling holes 6 and 6' formed therein, tertiary cores 8 and 8' inserted for coupling respectively into two coupling holes 6 and 6' of each of the associated magnetic induction secondary cores 5 and 5' opposite to each other, and responsive coils 7 and 7'. The ring permanent magnetic trains 2 and 2' are formed of 8 sets of magnets with alternating N and S poles, and magnets associated with each other in the axial direction have opposite polarities respectively and form a pair.

DESCRIPTION**TECHNICAL FIELD**

The present invention relates to generators, and particularly to a load-free generator which can maximise the generator efficiency by erasing or eliminating the secondary repulsive load exerted on the rotor during electric power generation.

BACKGROUND ART

The generator is a machine which converts mechanical energy obtained from sources of various types of energy such as physical, chemical or nuclear power energy, for example, into electric energy. Generators based on linear motion have recently been developed while most generators are structured as rotational type generators. Generation of electromotive force by electromagnetic induction is a common principle to generators regardless of their size or whether the generator is AC or DC generator.

The generator requires a strong magnet such as permanent magnet and electromagnet for generating magnetic field as well as a conductor for generating the electromotive force, and the generator is structured to enable one of them to rotate relative to the other. Depending on which of the magnet and the conductor rotates, generators can be classified into rotating-field type generators in which the magnetic field rotates and rotating-armature type generators in which the conductor rotates.

Although the permanent magnet can be used for generating the magnetic field, the electromagnet is generally employed which is formed of a magnetic field coil wound around a core to allow direct current to flow through them. Even if a strong magnet is used to enhance the rotational speed, usually the electromotive force produced from one conductor is not so great. Thus, in a generally employed system, a large number of conductors are provided in the generator and the electromotive forces generated from respective conductors are serially added up so as to achieve a high electric power.

As discussed above, a usual generator produces electricity by mechanically rotating a magnet (or permanent magnet) or a conductor (electromagnet, electrically responsive coil and the like) while reverse current generated at this time by magnetic induction (electromagnetic induction) and flowing through the coil causes magnetic force which pulls the rotor so that the rotor itself is subjected to unnecessary load which reaches at least twice the electric power production.

Fig.6 illustrates that the load as discussed above is exerted on a rotor in a rotating-field type generator mentioned above.

Referring to **Fig.6**, a permanent magnet train **104** is arranged about an axis of rotation **106** such that N poles and S poles are alternately located on the outer peripheral surface of the train. At a certain distance outward from the outer periphery of permanent magnet train **104**, a magnetic induction core **100** is arranged and a coil **102** is wound around magnetic induction core **100**.

As permanent magnet train **104** rotates, the magnetic field produced in the coil by permanent magnet train **104** changes to cause induced current to flow through coil **102**. This induced current allows coil **102** to generate a magnetic field **110** which causes a repulsive force exerted on permanent magnet train **104** in the direction which interferes the rotation of the magnet train.

For example, in the example shown in **Fig.6**, the S pole of magnetic field **110** faces permanent magnet train **104**. The S pole of permanent magnet train **104** approaches coil **102** because of rotation of permanent magnet train **104**, resulting in the repulsive force as described above.

If reverse current flows in a responsive coil of an armature wound around a magnetic induction core of a generator so that the resulting load hinders the rotor from rotating, reverse magnetic field of the armature responsive coil becomes stronger in proportion to the electricity output and accordingly a load corresponding to at least twice the instantaneous consumption could occur.

If electric power of 100W is used, for example, reverse magnetic field of at least 200W is generated so that an enormous amount of load affects the rotor to interfere the rotation of the rotor.

All of the conventional generators are subjected to not only a mechanical primary load, i.e. the load when the electric power is not consumed but a secondary load due to reverse current which is proportional to electric power consumption and consequently subjected to a load of at least twice the instantaneous consumption.

Such an amount of the load is a main factor of reduction of the electric power production efficiency, and solution of the problem above has been needed.

DISCLOSURE OF THE INVENTION

One object of the present invention is to provide a generator capable of generating electric power with high efficiency by cancelling out the secondary load except the mechanical load of the generator, i.e. cancelling out the load which is generated due to reverse current of a responsive coil of an armature wound around a magnetic induction core, so as to entirely prevent the secondary load from being exerted.

In short, the present invention is applied to a load-free generator including a rotational axis, a first ring magnet train, a second ring magnet train, a first plurality of first magnetic induction primary cores, a first plurality of second magnetic induction primary cores, a first responsive coil, and a second responsive coil.

The first ring magnet train has N poles and S poles successively arranged on an outer periphery of a first rotational orbit about the rotational axis. The second ring magnet train has magnets successively arranged on an outer periphery of a second rotational orbit about the rotational axis at a predetermined distance from the first rotational orbit such that the polarities of the magnets on the second rotational orbit are opposite to the polarities at opposite locations on the first rotational orbit respectively. The first plurality of first magnetic induction primary cores are fixed along a first peripheral surface of the first ring magnet train at a predetermined distance from the first peripheral surface. The first plurality of second magnetic induction primary cores are fixed along a second peripheral surface of the second ring magnet train at a predetermined distance from the second peripheral surface. A first plurality of first coupling magnetic induction cores and a first plurality of second coupling magnetic induction cores are provided in pairs to form a closed magnetic circuit between the first and second magnetic induction primary cores opposite to each other in the direction of the rotational axis. The first responsive coil is wound around the first coupling magnetic induction core. The second responsive coil is wound around the second coupling magnetic induction core, the direction of winding of the second responsive coil being reversed relative to the first responsive coil.

Preferably, in the load-free generator of the invention, the first ring magnet train includes a permanent magnet train arranged along the outer periphery of the first rotational orbit, and the second ring magnet train includes a permanent magnet train arranged along the outer periphery of the second rotational orbit.

Still preferably, the load-free generator of the present invention further includes a first plurality of first magnetic induction secondary cores provided on respective outer peripheries of the first magnetic induction primary cores and each having first and second coupling holes, and a first plurality of second magnetic induction secondary cores provided on respective outer peripheries of the second magnetic induction primary cores and each having third and fourth coupling holes. The first coupling magnetic induction cores are inserted into the first and third coupling holes to couple the first and second magnetic induction secondary cores, and the second coupling magnetic induction cores are inserted into the second and fourth coupling holes to couple the first and second magnetic induction secondary cores.

Alternatively, the load-free generator of the present invention preferably has a first plurality of first responsive coils arranged in the rotational direction about the rotational axis that are connected zigzag to each other and a first plurality of second responsive coils arranged in the rotational direction about the rotational axis that are connected zigzag to each other.

Alternatively, in the load-free generator of the present invention, preferably the first plurality is equal to 8, and the 8 first responsive coils arranged in the rotational direction about the rotational axis are connected zigzag to each other, and the 8 second responsive coils arranged in the rotational direction about the rotational axis are connected zigzag to each other.

Accordingly, a main advantage of the present invention is that two responsive coils wound respectively in opposite directions around a paired iron cores are connected to cancel reverse magnetic forces generated by reverse currents (induced currents) flowing through the two responsive coils, so that the secondary load which interferes the rotation of the rotor is totally prevented and thus a load-free generator can be provided which is subjected to just a load which is equal to or less than mechanical load when electric power production is not done, i.e. the rotational load even when the generator is operated to the maximum.

Another advantage of the present invention is that the reverse magnetic force, as found in the conventional generators, due to reverse current occurring when the rotor rotates is not generated, and accordingly load of energy except the primary gravity of the rotor and dynamic energy of the rotor is eliminated to increase the amount of electricity output relative to the conventional electric power generation system and thus enhance the electric power production and economic efficiency.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig.1 is a cross sectional view of a rotating-field type generator according to an embodiment of the present invention illustrating an arrangement a permanent magnet, magnetic induction cores and coils.

FIG. 1

Fig.2 is a partial schematic view illustrating a magnetic array of the permanent magnet rotor and an arrangement of one of magnetically responsive coils placed around that rotor in an embodiment of the present invention.

FIG. 2

Fig.3 illustrates a structure of the magnetically responsive coils and cores in the embodiment of the present invention.

Fig.4 is an enlarged plan view of magnetically sensitive cores and coil portions of the load-free generator of the present invention illustrating magnetic flow therethrough.

Fig.5 is an exploded view about a central axis showing the interconnection of magnetic field coils which are respectively wound around tertiary cores surrounding the permanent magnet rotor in FIG. 1 according to the present invention.

Fig.6 illustrates generation of the secondary load in a conventional generator.

BEST MODES FOR CARRYING OUT THE INVENTION

The structure and operation of a load-free generator according to the present invention are now described in conjunction with the drawings.

Fig.1 illustrates a cross sectional structure of the load-free generator of the invention perpendicular to a rotational axis **3**.

Fig.2 partially illustrates a cross sectional structure of the load-free generator of the invention in parallel to rotational axis **3**. Specifically, in **Fig.2**, only one of eight sets of magnetic induction primary cores **4** and **4'** arranged around rotational axis **3** as described below is representatively shown.

FIG. 1

Referring to **Fig.1** and **Fig.2**, the structure of the load-free generator of the invention is now described. Permanent magnet trains **2** and **2'** in ring forms are attached and fixed to respective left and right orbits **1** and **1'** provided relative to rotational axis **3** with a certain interval between them. Permanent magnet trains **2** and **2'** are fixed onto left and right orbits **1** and **1'** respectively such that the polarities on the outer peripheral surface of each magnet train relative to the rotational axis are alternately N poles and S poles. The permanent magnet trains are rotatable about the axis. Further, the facing polarities of respective permanent magnet train **2** and permanent magnet train **2'** relative to the direction of rotational axis **3** are arranged to be opposite.

FIG. 2

As shown in **Fig.2**, rotational axis **3** and a case **9** are joined by a bearing **10** at a certain distance from the permanent magnet trains **2** and **2'**.

At a predetermined distance from permanent magnet trains **2** and **2'**, magnetic induction primary cores **4** and **4'** with respective coils wound around them are fixed to case **9**.

In addition, magnetic induction secondary cores **5** and **5'** each having two coupling holes **6** and **6'** formed therein are structured by stacking and coupling a plurality of thin cores attached and fixed to magnetic induction primary cores **4** and **4'** respectively and the secondary cores are attached and fixed to case **9**.

Magnetic induction tertiary cores **8** and **8'** are inserted respectively into coupling holes **6** and **6'** of magnetic induction secondary cores **5** and **5'** so as to couple magnetic induction secondary cores **5** and **5'** of each other.

Responsive coils **7** and **7'** are wound in opposite directions to each other around respective magnetic induction cores **8** and **8'**.

Fig.3 illustrates a structure formed of magnetic induction secondary cores **5** and **5'**, magnetic induction cores **8** and **8'** and responsive coils **7** and **7'** viewed in the direction perpendicular to rotational axis **3**.

As explained above, the directions of windings of responsive coils **7** and **7'** are respectively opposite to each other around magnetic induction cores **8** and **8'** which couple magnetic induction secondary cores **5** and **5'**.

In the structure described in conjunction with **Fig.1**, **Fig.2** and **Fig.3**, when rotational axis **3** of the generator rotates, permanent magnetic trains **2** and **2'** accordingly rotate to generate magnetically sensitive currents (electromagnetically induced current) in responsive coils **7** and **7'** and the current thus produced can be drawn out for use.

FIG. 3

As shown in **Fig.3**, the coils are wound about magnetic induction cores **8** and **8'** respectively in the opposite directions in the generator of the present invention, and the directions of the magnetic fields generated by the flow of the induced currents are arranged such that the N pole and S pole alternately occurs around rotational axis **3**.

FIG. 4

Fig.4 illustrates magnetic fields induced in a set of magnetic induction secondary cores **5** and **5'**, magnetic induction cores **8** and **8'** and responsive coils **7** and **7'**.

At iron strips on both ends of respective magnetic induction secondary cores **5** and **5'**, a reverse current magnetic field is generated by responsive coil **7** upon the rotation of N and S poles of permanent magnet trains **2** and **2'** is in the direction of **MA** shown in **Fig.4**, for example, while a reverse current magnetic field generated by responsive coil **7** is in the direction of **MB** in **Fig.4**. Consequently, the reverse magnetic fields generated by the flow of currents cancel each other. The cores are formed of a plurality of iron strips in order to eliminate heat generated by eddy currents.

The magnetic field of the rotor thus has no dependence on the flow of currents, the load caused by the induced magnetisation phenomenon disappears, and energy of movement necessary for rotation against the mechanical primary load of the rotor itself is applied to the rotor.

At this time, a magnetic circuit including magnetic induction secondary cores **5** and **5'** and magnetic induction tertiary cores **8** and **8'** should be shaped into ".quadrature." form. If the circuit does not structured as ".quadrature." form, a part of the reverse magnetic field functions as electrical force which hinders the rotational force of the rotor.

Further, permanent magnet trains **2** and **2'** of the rotor are arranged to have opposite poles to each other on the left and right sides as shown in **Fig.2** so as to constitute the flow of magnetic flux. Each rotor has alternately arranged magnets, for example, eight poles are provided to enhance the generator efficiency.

More detailed description of the operational principle is given now. When the rotor in **Fig.1** rotates once, S and N poles of permanent magnets **2** and **2'** attached to the periphery of the rotor successively supply magnetic fields to induction primary cores **4** above, and magnetic field is accordingly generated in a path from one orbit of the rotor along induction primary core **4**, induction secondary core **5**, induction tertiary core **8**, induction secondary core **5'**, induction primary core **4'** to the other orbit of the rotor as shown in **Fig.2**.

Accordingly, current flows in the coils affected by this electric field to generate electric power. For example, if the generated power is used as generated output for switching on an electric light or for using it as motive energy, the current flowing through the coils generates the reverse magnetic fields. However, this reverse magnetic fields do not influence permanent magnets **2** and **2'** attached to the rotor in **Fig.2** since the reverse magnetic fields of the same magnitude respectively of S and N or N and S on both ends of magnetic induction secondary cores **5** and **5'** cancel out each other as shown in **Fig.4**. Because of this, the rotor is in a no-load state in which any resistance except the weight of the rotor itself and dynamic resistance is not exerted on the rotor.

Fig.5 illustrates a manner of connecting magnetically responsive coils **7** and **7'** wound around magnetic induction tertiary cores **8** and **8'** with eight poles.

Referring to **Fig.5**, according to a method of connecting magnetically responsive coils **7** and **7'**, line **1a1** of responsive coil **7'** (one drawn-out line of the wire coiled around a first magnetic induction core **8**) is connected to line **1a2'** (one drawn-out line of the wire coiled around a second magnetic induction core **8**), and then line **1a2** (the other drawn-out line of the wire coiled around a second magnetic induction core **8**) is connected to line **1a3'**, and subsequently lines **1a** and **1a'** are connected successively in zigzag manner to allow current to flow. Further, responsive coil **7** is arranged to connect lines represented by **1b1** in zigzag manner such that lines **1b** and **1b'** are successively connected. In this way, lines **1b**, **1b'** and lines **1a** and **1a'** of respective magnetically responsive coils **7** and **7'** are connected. As a whole, total four electric wires are drawn out for use.

When electric power is to be generated according to the present invention as described above, specifically, a closed circuit is formed by responsive coils **7** and **7'**, electric currents are induced in responsive coils **7** and **7'** wound around the magnetic induction cores of the generator, and the induced magnetic fields produced respectively by responsive coils **7** and **7'** could cause a great load which interferes the rotational force of the rotor. However, as shown in **Fig.4**, the direction of convolution of one coil **7** is opposite to that of the other coil **7'** so that the magnetic force generated by the reverse currents (induced currents) in responsive coils **7** and **7'** wound around magnetic induction core **4** is not transmitted to magnetic induction cores **8** and **8** accordingly no reverse magnetic force is transmitted to permanent magnets **2** and **2'**.

Therefore, each time the N poles and S poles alternate with each other because of the alternation of permanent magnets **2** and **2'** shown in **Fig.2**, the reverse magnetic forces in the right and left direction opposite to the direction of arrows denoted by **MA** and **MB** completely disappear as shown in **Fig.4**. Consequently, the reverse magnetic forces caused by the reverse currents are not influenced by permanent magnets **2** and **2'** and accordingly no load except the mechanical primary load is exerted on the generator of the invention.

As discussed above, the load-free generator of the present invention, secondary load except mechanical load of the generator, i.e. the load caused by the reverse currents flowing through the responsive coils can be nulled. With regard to this load-free generator, even if 100% of the current generated by magnetic induction (electromagnetic induction) is used, the magnetic secondary load due to the reverse currents except the mechanical primary load does not serve as load.

Although the number of poles of the rotor is described as **8** in the above description, the present invention is not limited to such a structure, and the invention can exhibit its effect when the smaller or greater number of poles is applied.

Further, although the magnet of the rotor is described as the permanent magnet in the above structure, the invention is not limited to such a case and the magnet of the rotor may be an electromagnet, for example.

In addition, although the description above is applied to the structure of the rotating-field type generator, the generator may be of the rotating-armature type.

EXPERIMENTAL EXAMPLE

More detailed description of the generator of the present invention is hereinafter given based on specific experimental examples of the invention.

The generator of the present invention and a conventional generator were used to measure the electric power production efficiency and the amount of load and compare the resultant measurements.

EXPERIMENTAL EXAMPLE 1

A 12-pole alternating current (AC) generator for battery charging was used, and the electricity output and the load when 50% of the electricity output was used as well as those when 100% of the electricity output was used were measured. The generator above is a single-phase AC motor and the employed power source was 220V, with 1750 rpm and the efficiency of 60%. The result of measurement using power of a motor of 0.5HP and ampere .times.volt gauge is shown in **Table 1**.

EXPERIMENTAL EXAMPLE 2

Measurement was done under the same conditions as those of experimental example 1 and a generator used was the one which was made according to the present invention to have the same conditions as those of the product of the existing model above. The result of measurement using ampere x volt gauge is shown in **Table 1**.

Table 1

Type of Generator	50% Electricity Used		100% Electricity Used	
	Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)
Conventional:	100	221	14	347
This invention:	100	220	183	200

(electricity output and load amount of the alternating current generators when 50% and 100% of the electricity were used)

From the result of Experimental Example 1 above, the reason for the remarkable reduction of the electricity output when the electricity consumption was 100% relative to the electricity consumption of 50% in the conventional generator is considered to be the significant increase of the repulsive load exerted on the generator when 100% of the electricity is used.

On the other hand, in the generator of the present invention, there was no appreciable difference in the amount of load between those cases in which 50% of the electricity was used and 100% thereof was used respectively. Rather, the amount of load slightly decreased (approximately 20W) when 100% of the electricity was used. In view of this, it can be understood that the amount of generated electric power of the generator of the present invention is approximately doubled as the electricity consumption increases, which is different from the conventional generator producing electric power which sharply decreases when the electricity consumption increases.

In conclusion, the amount of load above is supposed to be numerical value relative to the mechanical load of the generator as described above. Any secondary load except this, i.e. load due to the reverse currents generated in the armature responsive coils can be confirmed as zero.

EXPERIMENTAL EXAMPLE 3

12V direct current (DC) generators having similar conditions to those in experimental example 1 were used to make measurement under the same conditions (efficiency 80%). The result of the measurement is presented below.

Table 2

Type of Generator	50% Electricity Used		100% Electricity Used	
	Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)
Conventional:	103	290	21	298
This invention:	107	282	236	272

(electricity output and load amount of the alternating current generators when 50% and 100% of the electricity were used)

The DC generator has higher efficiency (80%) than that of the AC generator, while use of the brush increases the cost of the DC generator. When 100% of the electricity was used, the amount of load slightly decreased which was similar to the result shown in Table 1 and the electricity output was approximately at least 2.2 times that when 50% of the electricity was used.

EXPERIMENTAL EXAMPLE 4

A 220V single-phase alternating current (AC) generator (0.5HP) having similar conditions to those in experimental example 1 was used, and the rotation per minute (rpm) was changed to make measurement under the condition of 100% consumption of the generated electricity. The result of measurement is illustrated in the following **Table 3**.

Table 3

1750 rpm		3600 rpm		5100 rpm	
Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)
130	160	210	228	307	342

(amounts of generated electric power and load when the rotation per minute of the generator of the present invention was varied)

As shown in **Table 3** above, as the rotation per minute (rpm) increases as from 1750, 3600 to 5100, the amount of electric power increases respectively from 130, 210 to 307W and consequently the difference between the amount of generated electric power and the amount of load decreases to cause relative decrease of the amount of load as the rotation per minute (rpm) increases.

EXPERIMENTAL EXAMPLE 5

Measurement was done by changing the number of N and S poles of the permanent magnets of the invention under the same conditions as those of experimental example 1 and under the condition that 100% of the generated electricity was used.

The result of the measurement is illustrated below.

Table 4

2 poles		4 poles		8 poles	
Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)
80	152	130	200	265	296

(amounts of generated electric power and load when the number of poles of the permanent magnets of the generator of the invention was changed)

From **Table 4** above, it can be understood that as the number of poles increases, both of the amounts of generated electric power and load increase. However, the ratio of the amount of generated electric power to the amount of load monotonously increases. In the table above, in terms of the amount of load, only the mechanical primary load is exerted and electrical secondary is not exerted.

The increase of the number of poles causes increase, by the number of increased poles, in the number of lines of magnetic flux which coils traverse, and accordingly the electromotive force increases to increase the amount of generated electric power. On the other hand, the amount of mechanical load has a constant value regardless of the increase of the number of poles, so that the mechanical load amount relatively decreases to reduce the difference between the amount of load and the amount of generated electric power.

Detailed description of the present invention which has been given above is just for the purpose of presenting example and illustration, not for limitation. It will dearly be appreciated that the spirit and scope of the invention will be limited only by the attached scope of claims.

CONTINUOUS ELECTRICAL GENERATOR

This patent application shows the details of a device which it is claimed, can produce sufficient electricity to power both itself and external loads. It also has no moving parts.

ABSTRACT

A stationary cylindrical electromagnetic core, made of one piece thin laminations stacked to desired height, having closed slots radially distributed, where two three-phase winding arrangements are placed together in the same slots, one to the centre, one to the exterior, for the purpose of creating a rotational electromagnetic field by temporarily applying a three-phase current to one of the windings, and by this means, inducing a voltage on the second one, in such a way that the outgoing energy is a lot greater than the input. A return will feedback the system and the temporary source is then disconnected. The generator will run by itself indefinitely, permanently generating a great excess of energy.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates generally to electrical power generating systems. More specifically, the present invention relates to self-feeding electrical power generating units.

2. Description of Related Art

Since Nikola Tesla invented and patented his Polyphase System for Generators, Induction Motors and Transformers, no essential improvement has been made in the field. The generators would produce the polyphase voltages and currents by means of mechanical rotational movement in order to force a magnetic field to rotate across the generator's radially spaced windings. The basis of the induction motor system was to create an electro-magnetically rotating field, instead of a mechanically rotated magnetic field, which would induce voltages and currents to generate electromotive forces usable as mechanical energy or power. Finally, the transformers would manipulate the voltages and currents to make them feasible for their use and transmission for long distances.

In all present Electric Generators a small amount of energy, normally less than one percent of the outgoing power in big generators, is used to excite the mechanically rotated electromagnetic poles that will induce voltages and currents in conductors having a relative speed or movement between them and the polar masses.

The rest of the energy used in the process of obtaining electricity, is needed to move the masses and to overcome the losses of the system: mechanical losses; friction losses; brushes losses, windage losses; armature reaction losses; air gap losses; synchronous reactance losses; eddy current losses; hysteresis losses, all of which, in conjunction, are responsible for the excess in power input (mechanical power) required to generate always smaller amounts of electric power.

SUMMARY OF THE INVENTION

The **Continuous Electrical Generator** consists of a stationary cylindrical electromagnetic core made of one piece thin laminations stacked together to form a cylinder, where two three-phase windings arrangements are placed in the same slots not having any physical relative speed or displacement between them. When one of the windings is connected to a temporary three-phase source, an electromagnetic rotating field is created, and the field this way created will cut the stationary coils of the second winding, inducing voltages and currents. In the same way and extent as in common generators, about one percent or less of the outgoing power will be needed to keep the rotational magnetic field excited.

In the **Continuous Electrical Generator** there are no mechanical losses; friction losses; brush losses; windage losses; armature reaction losses; or air gap losses, because there is not any movement of any kind. There are: synchronous reactance losses, eddy current losses and hysteresis losses, which are inherent to the design, construction and the materials of the generator, but in the same extent as in common generators.

One percent or less of the total energy produced by present electric generators goes to create their own magnetic field; a mechanical energy that exceeds the total output of present generators is used to make them rotate in the process of extracting electrical currents from them. In the **Continuous Electrical Generator** there is no need for movement since the field is in fact already rotating electro-magnetically, so all that mechanical energy will not be needed. Under similar conditions of exciting currents, core mass and windings design, the **Continuous Electrical Generator** is significantly more efficient than present generators, which also means that it can produce significantly more than the energy it needs to operate. The **Continuous Electrical Generator** can feedback the system, the temporary source may be disconnected and the Generator will run indefinitely.

As with any other generator, the **Continuous Electrical Generator** may excite its own electromagnetic field with a minimum part of the electrical energy produced. The **Continuous Electrical Generator** only needs to be started up by connecting its inducting three-phase windings to a three-phase external source for an instant, and then to be disconnected, to start the system as described herein. Then, disconnected, it will run indefinitely generating a great excess of electric power to the extent of its design.

The **Continuous Electrical Generator** can be designed and calculated with all mathematical formulas in use today to design and calculate electrical generators and motors. It complies with all of the laws and parameters used to calculate electrical induction and generation of electricity today.

Except for the Law of Conservation of Energy, which, by itself, is not a mathematical equation but a theoretical concept and by the same reason does not have any role in the mathematical calculation of an electrical generator of any type, the **Continuous Electrical Generator** complies with all the Laws of Physics and Electrical Engineering. The **Continuous Electrical Generator** obligates us to review the Law of Conservation of Energy. In my personal belief, the electricity has never come from the mechanical energy that we put into a machine to move the masses against all oppositions. The mechanical system is actually providing the path for the condensation of electricity. The **Continuous Electrical Generator** provides a more efficient path for the electricity.

DETAILED DESCRIPTION OF THE INVENTION

The present invention is a Continuous and Autonomous Electrical Generator, capable of producing more energy than it needs to operate, and which provides itself the energy needed to operate. The basic idea consists in the induction of electric voltages and currents without any physical movement by the use of a rotational magnetic field created by a three-phase stator connected temporarily to a three-phase source, and placing stationary conductors on the path of said rotational magnetic field, eliminating the need of mechanical forces.

FIG. 1

The basic system can be observed in **Fig.1**, which shows one embodiment of the present invention. There is a stationary ferromagnetic core **1** with a three-phase inducing windings **3**, spaced 120 degrees and connected in Y **6** in order to provide a rotating electromagnetic field, when a three-phase voltage is applied; for the case, a two-pole arrangement. Inside this core **1** there is a second stationary ferromagnetic core **2**, with no space between them, this is, with no air-gap. This second core **2** has also a three-phase stationary winding arrangement (**4a** in **Fig.4b** and **4b** in **Fig.2**), aligned as shown in **Fig.1** and **Fig.2** with the external core inducing windings **3**. There is not any movement between the two cores, since there is no air-gap between them.

There is no shaft on either core since these are not rotating cores. The two cores can be made of stacked insulated laminations or of insulated compressed and bonded ferromagnetic powder. The system works either way, inducing three-phase voltages and currents on the stationary conductors **4a** of the internal windings **4b**, applying three-phase currents to terminals **A 5a**, **B 5b** and **C 5c** of the external windings **3**; or inducing three-phase voltages and currents on the external windings **3**, by applying three-phase currents to the terminals **T1 7a**, **T2 7b** and **T3 7c**, of the internal windings **4b**. When a three-phase voltage is applied to terminals **A 5a**, **B 5b** and **C 5c**, the currents will have the same magnitude, but will be displaced in time by an angle of 120 degrees. These currents produce magneto motive-forces, which, in turn, create a rotational magnetic flux. The arrangements may vary widely as they occur with present alternators and three-phase motors, but the basics remain the same, a stationary but electro-magnetically rotating magnetic field, inducing voltages and currents on the stationary conductors placed on the path of said rotating magnetic field. The diagram is showing a two-pole arrangement for both windings, but many other arrangements may be used, as in common generators and motors.

FIG. 2

Fig.2 shows the three-phase arrangement of the internal winding **4b** which has provided, in practice, symmetrical voltages and currents, due to a space angle of 120 degrees. It is similar to a two-pole arrangement. Many other three-phase or poly-phase arrangements may be used. Wherever a conductor is crossed by a rotational magnetic field, a voltage will be induced across its terminals. The interconnections depend on the use that we will give to the system. In this case, we will have a three-phase voltage in terminals **T1 7a**, **T2 7b** and **T3 7c** and a neutral **8**. The outgoing voltage depends on the density of the rotational magnetic flux, the number of turns of the conductor, the frequency (instead of the speed) and the length of the conductor crossed by the field, as in any other generator.

Fig.3 shows an alternate embodiment of the present invention in which the generator is made from multiple one-piece laminations **9**, stacked as a cylinder to the desired height. This embodiment can also be made of a one-piece block of compressed and bonded insulated ferromagnetic powder. The same slot **10** will accommodate the internal **4a/4b** and the external windings **3**, that is, the inducing and the induced windings (see **Fig.5**). In this case, a 24-slot laminate is shown, but the number of slots may vary widely according to the design and needs.

Fig.4 shows a two-piece single laminate for another alternate embodiment of the present invention. For practical effects the lamination can be divided into two pieces **9a**, **9b**, as shown, to facilitate the insertion of the coils. Then, they are solidly assembled without separation between them, as if they were only one piece.

The laminates described above may be constructed with thin (0.15 mm thick or less) insulated laminations **9** or **9a** and **9b** of a high magnetic permeability material and low hysteresis losses such as Hiperco 50A, or similar, to reduce losses or with compressed electrically isolated ferromagnetic powder, which has lower eddy current losses and also may have low hysteresis losses, which can make the generator highly efficient.

OPERATING THE GENERATOR

The **C**ontinuous **E**lectrical **G**enerator as described and shown in the following drawings is designed and calculated to produce a strong rotating electromagnetic field with low exciting currents. By using a laminated material, such as the said Hiperco 50A, we can achieve rotating magnetic fields above two Teslas, since there are no air gap losses, mechanical losses, windage losses, armature reaction losses, etc. as said before. This may be obtained by applying a temporary three-phase current to the terminals **A**, **B** and **C** 12 of the inducing coils 13, 14 and 15 (5a, 5b and 5c in Fig.1), spaced 120 degrees from each other (see Fig.5).

FIG. 5

Fig.5 shows the spatial distribution of the inducing windings 13, 14 and 15, as well as the induced windings 18a, 18b, 19a, 19b, 20a and 20b. Both, the inducing and the induced windings are placed in the same slots 10 or 16 and 17, with similar arrangements. Even though the system works in both directions, the better configuration seems to be to place the inducing windings 13, 14 and 15, to the centre and the induced windings 18a, 18b, 19a, 19b, 20a and 20b, to the exterior, since small windings will be needed to induce a very strong rotational magnetic field, due to the small losses involved in the process, and in exchange, bigger and powerful windings will be needed to extract all the energy that the system will provide. Both windings are connected in Y (not shown), but they can be connected in different ways, as any other generator. These arrangements are equivalent to the arrangements shown for the embodiment in **Fig.1** and **Fig.2**.

The inducing coils 13, 14 and 15 are designed and calculated so that the generator may be started with common three-phase lines voltages (230 Volts 60 Hz per phase, for example). If the local lines voltages are not appropriate, we can control the voltage to the designed level by means of a three-phase variable transformer, an electronic variator or inverter etc. Once we have such strong magnetic field rotating and crossing the stationary induced coils 18a, 18b, 19a, 19b, 20a and 20b, a three-phase voltage will be induced across terminals **T1**, **T2**, **T3** and **N** 21 in proportion to the magnetic flux density, the number of turns in the coils, the frequency used (instead of the speed), the length of the conductors cut by the rotating field, as in any other alternator. We can connect, as we desire in Y or delta, etc., as in any other alternator or generator. The outgoing currents will be three-phase currents (or poly-phase currents depending on the arrangement) and we can have a neutral 21 if we are using a Y connection, as in any other alternator.

The outgoing alternate voltages and currents are perfect sinusoidal waves, perfectly spaced in time, and totally symmetrical. The voltages and currents obtained by this method are usable in any conventional manner. Any voltage can be produced, depending on the design.

Fig.6 shows the magnetic flux pattern produced by the three-phase inducing windings 13, 14 and 15. This pattern is similar to the pattern of an induction motor's stators. Since there is no air gap; the whole path for the magnetic flux is homogeneous with no change in materials. The core is made of thin insulated laminations of a high magnetic permeability and low hysteresis loss material; eddy current losses are minimal due to the thin lamination. There are no counter fluxes or armature reactions thus the magnetic flux may be near to saturation with a small exciting current or input energy. Due to the time differential between the three phases and the spatial distribution of the inducing windings, a rotational magnetic field will be created in the core, as shown in **Fig.7**.

Once the generator is started, a small part of the energy obtained is sent back (**Fig.8** and **Fig.9**) to feed the inducting coils **3** (in **Fig.1**) or **13, 14** and **15** (in **Fig.5**), as in any other auto-excited alternator or generator. Of course voltages and phases should be perfectly identical and aligned, and if necessary the feedback voltages should be controlled and handled by means of variable transformers, electronic variators, phase shifters (to align phases) or other type of voltage or phase controllers.

One possible method consists of the use of an electronic converter or variator **25** which initially converts two or three lines of alternating current **24** to direct current by an electronic rectifier **26** and then, electronically, converts the direct current **27** to three-phase current **28** to supply three-phase currents spaced in time 120 degrees for the electromagnetic fields **A, B** and **C 3**. Some variators or converters can accept two lines of voltage, while others will accept only a three-phase line voltage. This embodiment uses a variator of 3 kVA that accepts two 220-volt lines.

The rotational magnetic field created by the currents going through the inducting three-phase windings **13, 14** and **15**, will induce a voltage across the terminals **T1, T2, T3, N, 29 (7a, 7b, 7c, 8** in **Fig.2**). Then, from the outgoing current lines **29**, a derivation is made **30** to feed back the system, converting the feed back alternate currents, by means of electronic diode rectifiers **31**, to direct current **32** and then feed back the electronic converter or variator **25** to the DC terminals of the electronic rectifier **26** (See **Fig.8**). Once the feedback is connected, the **Continuous Electrical Generator** may be disconnected from the temporary source **24**, and will continue generating electric energy indefinitely.

In **Fig.9**, an alternate embodiment of the **Continuous Electrical Generator** can be observed. The basic principles remain the same as for the embodiment described above and shown in **Fig.1** and **Fig.2**. The basic differences are in the shape of the laminations and the physical distribution of the windings, as discussed and shown previously. A variation of the feedback, using a variable and shifting transformers is also shown.

The ferromagnetic core **11** is made of one-piece laminates **9** as shown in **Fig.3** (or two for convenience **9a, 9b** as shown in **Fig.4**) stacked to the desired height. The slots **10**, as indicated before, will accommodate both the inducting **13, 14** and **15** and the induced **18a-b, 19a-b** and **20a-b** windings in the same slot **10** or **16** and **17**. The incoming three phase lines **12** feed the inducting three-phase windings **13, 14** and **15**. They are fed, initially by the temporary source **33** in the first instance, and by the three-phase return **34** once the generator is running by itself.

The inducting windings **13, 14** and **15** have a two-pole arrangement, but many other three-phase or poly-phase arrangements can be made to obtain an electromagnetic rotating field. These windings are connected in Y (not shown) in the same way shown for the embodiment shown in **Fig.1, Fig.2** and **Fig.8**, but may be connected in many different ways. The inducting windings **13, 14** and **15** are located in the internal portion **16** of the slot **10** (**Fig.5**).

The induced windings **18a-b, 19a-b** and **20a-b** have a two-pole arrangement, exactly equal to the arrangement for the inducting windings **13, 14** and **15**, but many other arrangements can be made depending on the design and the needs. The induced windings must be calculated in a way that the generator will have the lowest possible synchronous reactance and resistance. In this way, most of the outgoing power will go to the charge instead of staying to overcome the internal impedance. These windings are connected in Y to generate a neutral **21**, in the same way shown in the embodiment of the present invention shown in **Fig.2**, but may be connected in different ways according to the needs. The induced windings **18a-b, 19a-b** and **20a-b** are located in the external portion **17** of the slot **10**.

The outgoing three-phase and neutral lines **21** come from the induced windings **18a-b, 19a-b** and **20a-b**. The rotational magnetic field created in the core (see **Fig.6 & Fig.7**) by the inducting windings **13, 14** and **15**, induces a voltage across the terminals **T1, T2** and **T3**, plus a neutral, **29**. From each of the three-phase outgoing lines **21**, a return derivation **34** is made to feedback the system.

The temporary three-phase source **33** is temporarily connected to terminals **A, B** and **C 12**. The **Continuous Electrical Generator** must be started with an external three-phase source for an instant, and then disconnected.

Even though the return lines voltage can be calculated and obtained precisely by tabbing the induced windings at the voltage required by the inducting windings (according to the design), it may be convenient to place a three-phase variable transformer or other type of voltage controller **35** in the middle for more precise adjustment of the return voltage.

Placed after the variable transformer **35**, the three-phase shifting transformer **36** will correct and align any phase shift in the voltage and currents angles, before the return is connected. This system functions similarly to the system shown in **Fig.8** which uses a variator or a converter **25**.

Once the voltage and phases are aligned with the temporary source **33**, the return lines **34** are connected to the incoming lines **A, B** and **C 12** at feedback connection **37** and the temporary source **33** is then disconnected. The **Continuous Electrical Generator** will remain working indefinitely without any external source of energy, providing a great excess of energy permanently.

The outgoing electric energy provided by this system has been used to produce light and heat, run poly-phase motors, generate usable mono-phase and poly-phase voltages and currents, transform voltages and currents by means of transformers, convert the alternate outgoing poly-phase currents to direct current, as well as for other uses. The electricity obtained by the means described is as versatile and perfect as the electricity obtained today with common electric generators. But the **Continuous Electrical Generator** is autonomous and does not depend on any other source of energy but itself once it is running; may be carried anywhere with no limitations; it can be constructed in any size and provides any amount of electricity indefinitely, according to the design.

The **Continuous Electrical Generator** is and will be a very simple machine. The keystones of the systems reside in the ultra-low losses of a non-movement generation system, and in a very low synchronous reactance design.

The induced windings must be calculated in a way that the generator may have the lowest possible synchronous reactance and resistance. In this way, most of the outgoing power will go to the charge instead of staying to overcome the internal impedance.

SEMICONDUCTOR COMPOSITIONS

This patent application shows the details of a device which it is claimed, can produce electricity via a solid-state oscillator. It should be noted that while construction details are provided which imply that the inventor constructed and tested several of these devices, this is only an application and not a granted patent.

ABSTRACT

A resonance oscillator electric power pack for operating a flash lamp, for example, or other electrically operated device, operates without moving mechanical parts or electrolytic action. The power pack is contained in a cylindrical metal envelope and in a preferred embodiment, is coupled to a relaxation oscillator and an incandescent lamp. Within the envelope, and insulated from it, is a semiconductor tablet having a metal base connected to the external circuit. A metal probe makes contact with a point on the semiconductor tablet and with a cylindrical ferrite rod, axially aligned with the envelope. Wound about the ferrite rod, are concentric helical coils designated as a 'primary' with many turns, and a 'secondary' with fewer turns than the primary.

One end of the primary coil is connected to the probe and the other end is connected to the secondary coil. the leads from the secondary coil are connected to the relaxation oscillator via an adjustable capacitor. Oscillation within the envelope is resonance amplified, and the induced voltage in the secondary coil is rectified for application to the relaxation oscillator and lamp. Selenium and germanium base semiconductor compositions including Te, Nd, Rb and Ga in varying proportions are used for the tablet.

BACKGROUND OF THE INVENTION

This is a continuation-in-part of my co-pending patent application Serial No. 77,452, filed 2nd October 1970, entitled "Electric Power Pack" now abandoned.

In many situations it is desirable to have a source of electric power which is not dependent on wires from a central generating station, and therefore, portable power supplies having no moving parts have been employed. typically, such portable power packs have been primary or secondary electrolytic cells which generate or store electrical energy for release by chemical action. Such batteries have a limited amount of contained energy and must often be replaced at frequent intervals to maintain equipment in operation.

Thus, as one example, flashing lights are commonly used along highways and other locations to warn of dangerous conditions. These flashing lights in remote locations are typically incandescent or gas-discharge lamps connected to some type of relaxation oscillator powered by a battery. The batteries employed in such blinking lights have a limited lifetime and must be periodically replaced, typically each 250 to 300 hours of operation. This involves a rather large labour cost in replacing the expended batteries with fresh ones and additional cost for primary cells or for recharging secondary cells. It is desirable to provide an electric power pack capable of providing a sufficient quantity of electrical energy over a prolonged period of time so that the requirement for periodic replacement of the electrolytic cells can be avoided. Such a power pack is valuable even if appreciably more expensive than batteries because of the greatly reduced labour costs required for periodic replacements.

BRIEF SUMMARY OF THE INVENTION

There is provided in practice of this invention according to a preferred embodiment, semiconductive compositions selected from the Group consisting of:

Selenium with, from 4.85% to 5.5% Tellurium, from 3.95% to 4.2% Germanium, from 2.85% to 3.2% Neodymium, and from 2.0% to 2.5% Gallium.

Selenium with, from 4.8% to 5.5% Tellurium, from 3.9% to 4.5% Germanium, from 2.9% to 3.5% Neodymium and from 4.5% to 5% Rubidium, and

Germanium with, from 4.75% to 5.5% Tellurium, from 4.0% to 4.5% Neodymium and from 5.5% to 7.0% Rubidium.

DRAWINGS

These and other features and advantages of the invention will be appreciated and better understood by reference to the following detailed description of a preferred embodiment when considered in conjunction with the following drawings:

Fig.1 illustrates in exploded schematic, a flashing lamp connected to an electric power supply constructed according to the principles of this invention.

Fig.2 illustrates in longitudinal cross-section, the power pack of Fig.1

Fig.3 is an electric circuit diagram of the system.

DESCRIPTION

Fig.1 illustrates schematically, a typical flashing lamp having a power supply constructed according to the principles of this invention. As illustrated in this preferred embodiment, an electric power pack **5**, is connected electrically to a relaxation oscillator circuit (shown only schematically) on a conventional printed-circuit board **6**.

The power pack **5** and the printed-circuit board are mounted in a metal box **7**, which has a transverse partial partition **8**, which creates two spaces, one for the power pack and the other for the printed-circuit board which is prevented from contacting the metal box by any convenient insulating mounting. Preferably, these components are potted in place in a conventional manner.

A cover **9**, having mounting lugs **10**, is riveted on to the box after assembly. A small terminal strip **11**, mounted on one side of the box **7**, provides electrical contacts for connection to a load such as an incandescent lamp (not shown in Fig.1). the lamp provides a flash of light when the relaxation oscillator switches. Although the described system is employed for a flashing lamp, it will be apparent that other loads may be powered by the invention.

In **Fig.2**, the electric power pack **10**, is illustrated in longitudinal cross-section and has dimensions as follows: These dimensions are provided by way of example for powering a conventional flashing lamp and it will be clear that other dimensions may be used for other applications. In particular, the dimensions may be enlarged in order to obtain higher power levels and different voltage or current levels. The power pack is comprised of a cylindrical metal tube **16**, having closely fitting metal caps **17** at each end, which are preferably sealed to the tube after the internal elements are inserted in place. The metal tube **16** and caps **17**, which are preferably of aluminium, thus form a closed conductive envelope, which in a typical embodiment, has an inside diameter of about 0.8 inch and a length of about 2.25 inches.

Mounted within one end of the envelope is a plastic cup **18**, the dimensions of which are not critical, however, a wall thickness of at least 1/16 inch is preferred. Mounted within the plastic cup **18** is a semiconductor tablet **19** having a flat base and somewhat domed opposite side. The composition of the semiconductor tablet **19** is set out in greater detail below. Typically, the semiconductor tablet has a mass of about 3.8 grams. A metal disc **21** is positioned beneath the base of the tablet **19** in the cup **18**, and is preferably adhesively bonded inside the cup. The metal disc is tightly fitted to the base of the tablet so that good electrical contact is obtained over a substantial area of the semiconductor.

An ear **22** on one edge of the disc is soldered to a wire **23**, which extends through a short insulating sleeve **24** which passes through a hole in the side of the metal envelope. The insulating sleeve **24** acts as a grommet and ensures that there is no damage to the insulation of wire **23** and subsequent accidental short circuiting between the wire and the metal envelope. Preferably, the insulating sleeve **24** is sealed with a small amount of plastic cement or the like, in order to maintain clean air within the cylindrical envelope. Two other openings for leads through the tube **16**, as mentioned below, are also preferably sealed to maintain cleanliness within the envelope.

A pair of circular metal discs **26**, are fitted inside tube **16** and are preferably cemented in place to prevent shifting. The two discs **26**, are equally spaced from the opposite ends of the envelope and are spaced apart by slightly more than 1.15 inches. Each of the discs has a central aperture **27**, and there is a plurality of holes **28**, extending through the disc in a circular array midway between the centre of the disc and its periphery. The holes **28** are preferably in the size range of about 0.01 to 0.06 inch in diameter and there are 12 on each disc located at 30⁰ intervals around the circle.

The two discs **26** divide the interior of the cylindrical envelope into three chambers, and the pattern of holes **28** provides communication between the chambers and affects the electrical properties of the cavity. It is believed that the pattern of holes affects the inductive coupling between the cavities inside the envelope and influences the oscillations in them.

Although an arrangement of 12 holes at 30⁰ centres has been found particularly advantageous in the illustrated embodiment, it is found in other arrangements that a pattern of 20 holes at 18⁰ centres or a pattern of 8 holes at 45⁰ centres, provides optimum operation. In either case, the circle of holes **28** is midway between the centre and the periphery of the disc.

Mounted between the discs **26** is a plastic spool **29** which has an inside distance of 1.1 inches between its flanges. The plastic spool **29** preferably has relatively thin walls and an internal bore diameter of 1/8 inch. A plastic mounting plug **31**, is inserted through the central aperture **27** of the disc **26** farthest from the semiconductor table **19**, and into the bore of the spool **29**. The plastic plug **31** is preferably cemented to the disc **26** in order to hold the assembly together.

Also mounted inside the bore of spool **29** is a cylindrical ferrite core **32**, about 1/8 inch diameter and 3/4 inch long. Although a core of any magnetic ferrite is preferred, other ferromagnetic materials having similar properties can be used if desired. The core **32**, is in electrical contact with a metal probe **33** about 1/4 inch long. Half of the length of the probe **33** is in the form of a cylinder positioned within the spool **29**, and the other half is in the form of a cone ending in a point **34** in contact with the domed surface of the semiconductor tablet **19** where it makes an electrical contact with the semiconductor in a relatively small point.

Electrical contact is also made with the probe **33** by a lead **36**, which passes through one of the holes **28** in the disc **26** nearer to the semiconductor tablet and thence to a primary coil **37**, wound on the plastic spool **29**. The primary coil **37** is in the form of 800 to 1000 turns wound along the length of the spool, and the lead **38** at the opposite end of the coil **37** is soldered to one of the external leads **39** of the power pack. This lead **39** proceeds through one of the holes **28** in the disc farthest from the semiconductor tablet **19**, and through an insulating sleeve **41** in the metal tube **16**.

The lead **39** is also connected to one end of a secondary coil **42** which is composed of 8 to 10 turns around the centre portion of the primary coil **37**. A thin insulating sheet **43** is provided between the primary and secondary coils. The other lead **44** from the secondary coil passes through one of the holes **28** in the disk nearer the semiconductor tablet and thence through an insulating sleeve **46** through the wall of the tube **16**.

Fig.3 illustrates schematically, the electrical circuit employing an electric power pack constructed according to the principles of this invention. At the left hand side of **Fig.3**, the arrangement of elements is illustrated in a combination of electrical schematic and mechanical position inside tube **16** for ready correlation with the embodiment illustrated in **Fig.2**. Thus, the semiconductor tablet **19**, probe **33** and ferrite core **32** are shown in both their mechanical and electrical arrangement, the core being inductively coupled to the coils **37** and **42**. The lead **23** from the metal base of the semiconductor tablet **19**, is connected to a variable capacitor **47**, the other side of which is connected to the lead **44** from the secondary coil **42**. The lead **44** is also connected to a rectifying diode **48** shunted by a high value resistor **49**.

It will be seen that the variable capacitor **47** is in a tank circuit with the inductive coils **37** and **42** which are coupled by the ferrite core **32**, and this circuit also includes the semiconductor tablet **19** to which point contact is made by the probe **33**. The mechanical and electrical arrangement of these elements provides a resonant cavity in which resonance occurs when the capacitor **47** is properly trimmed. The diode **48**, rectifies the oscillations in this circuit to provide a suitable DC for operating an incandescent lamp **50** or similar load.

The rectifying diode **48** is connected to a complementary-symmetry relaxation circuit for switching power to the load **50**. The diode is connected directly to the collector of a PNP transistor **51** which is in an inverted connection. the emitter of the PNP transistor is connected to one side of the load **50** by way of a timing resistor **55**. The base of the transistor **51** is connected by way of a resistor **52** and a capacitor **56** to the collector of an NPN transistor **53**, the emitter of which is connected to the other side of the load **50**. The base of the NPN transistor **53** is coupled to the diode by a resistor **54**. The emitter of the PNP transistor **51** is fed back to the base of the NPN transistor **53** by the resistor **55**. Current flow through the lamp **50** is also limited by a resistor **57** which couples one side of the lamp and the emitter of the NPN transistor **53** to the two coils **37** and **42** by way of the common lead **39**.

The electrical power pack is believed to operate due to a resonance amplification once an oscillation has been initiated in the cavity, particularly the central cavity between the discs **26**. This oscillation, which apparently rapidly reaches amplitudes sufficient for useful power, is then half-wave rectified for use by the diode **48**. With such an arrangement, a voltage level of several volts has been obtained, and power sufficient for intermittent operation of a lamp requiring about 170 to 250 milliwatts has been demonstrated. The resonant amplification is apparently due to the geometrical and electrical combination of the elements, which provide inductive coupling of components in a suitable resonant circuit. This amplification is also, at least in part, due to unique semiconductor properties in the tablet **19**, which has electronic properties due to a composition giving a unique atomic arrangement, the exact nature of which has not been measured.

The semiconductor tablet has electronic properties which are determined by it's composition and three such semiconductors satisfactory for use in the combination have been identified. In two of these, the base semiconductor material is selenium provided with suitable dopant elements, and in the third, the base element is germanium, also suitably doped. The semiconductor tablets are made by melting and casting in an arrangement which gives a large crystal structure. It has not been found necessary to provide a selected crystal orientation in order to obtain the desired effects.

A preferred composition of the semiconductor includes about 5% by weight of tellurium, about 4% by weight of germanium, about 3% by weight of neodymium and about 4.7% by weight of rubidium, with the balance of the composition being selenium. Such a composition can be made by melting these materials together or by dissolving the materials in molten selenium.

Another highly advantageous composition has about 5% by weight of tellurium, about 4% by weight of germanium, about 3% by weight of neodymium, and about 2.24% by weight of gallium, with the balance being selenium. In order to make this composition, it is found desirable to add the very low melting point gallium in the form of gallium selenide rather than elemental gallium.

A third suitable composition has about 5% by weight of tellurium, about 4% by weight of neodymium, about 6% by weight of rubidium, with the balance being germanium. These preferred compositions are not absolute and it has been found that the level of dopant in the compositions can be varied within limits without significant loss of performance. Thus, it is found that the proportion of tellurium in the preferred composition can range from about 4.8% to about 5.5% by weight; the germanium can range from about 3.9% to 4.5% by weight; neodymium can range from about 2.9% to 3.5% by weight, and rubidium can vary from about 4.5% to 5.0% by weight. The

balance of the preferred composition is selenium although it has also been found that nominal impurity levels can be tolerated and no great care is required in preventing minor contamination.

The other selenium base composition useful in practice of this invention can have a tellurium concentration in the range of from about 4.85% to 5.5% by weight, germanium in the range of from about 3.95% to 4.2% by weight, neodymium in the range of from about 2.85% to 3.2% by weight, and gallium in the range of from about 2.0% to 2.5% by weight. As in the preferred composition, the balance is selenium and nominal impurity levels can be tolerated. It is preferred to add the gallium in the form of gallium selenide rather than as elemental gallium with a corresponding decrease in the selenium used to make up the composition.

The above selenium base compositions are easier to make and less expensive than the germanium base composition and are therefore preferable for most applications. It is found that these are particularly suited for relatively small semiconductor tablets up to about 1 inch or a little less. For relatively large tablets, it is preferred to use the germanium base composition.

The germanium base composition has a tellurium level in the range of from about 4.75% to 5.5% by weight, neodymium in the range of from about 4.0% to 4.5% by weight, and rubidium in the range of from about 5.5% to 7.4% by weight. It is also found that it is of greater importance to maintain purity of the germanium base compositions than the selenium base compositions. Although the exact purity levels have not been ascertained, it is in excess of 99%.

It has been found that it is not necessary to have single crystals in the semiconductor tablets and any convenient grain size in excess of about 1 millimetre appears satisfactory. In the above compositions, when the recited ranges are exceeded, oscillation in the power pack drops off rapidly and may cease altogether.

The reasons that these compositions are satisfactory in the arrangement providing resonance amplification has not been determined with certainty. It is possible that the semiconductor serves as a source of electrons for providing an oscillating current in the circuit. This is, of course, combined with a relatively large area contact to one side of the semiconductor tablet, and a point contact on another area. Any resonant current in the coils wound on the ferrite rod, induces a varying magnetic field in the resonant cavity, and the electrical connection between the ferrite rod and the metal probe, provides a feedback of this oscillation to the semiconductor tablet.

it should particularly be noted that the oscillation in the circuit does not commence until it is initiated by an oscillating signal. In order to accomplish this, it is only necessary to apply a few millivolts of AC for a few seconds to the semiconductor tablet and the associated coils coupled to it. The initial signal applied to the base of the semiconductor tablet and the lead 39 is preferably in the frequency range of 5.8 to 18 Mhz and can be as high as 150 Mhz. Such a signal can be applied from any conventional source and no great care appears necessary to provide a single frequency signal or to eliminate noise. Once such energisation has been applied to the circuit and oscillations initiated, it does not appear to be necessary to apply such a signal again. This is apparently due to the feedback provided by the ferrite rod to the probe which makes contact with the semiconductor tablet.

Energy is, of course, dissipated in the lamp, or other utilisation device, as the combination operates. Such energy may come from deterioration of the semiconductor tablet as oscillations continue; however, if there is any such deterioration, it is sufficiently slow that a power source may be operated for many months without attendance. Such a source of energy may be augmented by ambient Radio Frequency radiation, coupled into the resonant cavity by the external leads. This is a surprising phenomenon because the leads are small compared to what would normally be considered an adequate antenna, and it is therefore postulated that stimulated amplification may also be a consequence of the unique electronic configuration of the semiconductors having the compositions specified above.

Although only one embodiment of electric power pack constructed according to principles of this invention has been described and illustrated here, many modifications and variations will be apparent to one skilled in the art. Thus, for example, a larger power pack may be axially arranged in a cylindrical container with various electronic elements arranged in the annular space. It is therefore to be understood that other configurations are included within the scope of the invention.

EDWIN GRAY

US Patent 3,890,548

June 17, 1975

Inventor: Edwin V. Gray snr.

PULSED CAPACITOR DISCHARGE ELECTRIC ENGINE

Please note that this is a re-worded extract from Edwin Gray's Patent 3,890,548. It describes his high voltage motor and the circuitry used to drive it. Please be aware that the underlying technology was developed by Marvin Cole and Edwin Gray did not understand it. Also, Edwin wanted at all costs to conceal any useful technology while getting patents to encourage investors, so please understand that this patent is not intended to tell you how to make a working system of this type.

SUMMARY OF THE INVENTION:

This invention relates to electric motors or engines, and more particularly to a new electric machine including electromagnetic poles in a stator configuration and electromagnetic poles in a rotor configuration, wherein in one form thereof, the rotor is rotatable within the stator configuration and where both are energised by capacitor discharges through rotor and stator electromagnets at the instant of the alignment of a rotor electromagnet with a stator electromagnet. The rotor electromagnet is repelled from the stator electromagnet by the discharge of the capacitor through the coils of both the rotor and stator electromagnets at the same instant.

In an exemplary rotary engine according to this invention, rotor electromagnets may be disposed 120 degrees apart on a central shaft and major stator electromagnets may be disposed 40 degrees apart in the motor housing about the stator periphery. Other combinations of rotor elements and stator elements may be utilised to increase torque or rate of rotation.

In another form, a second electromagnet is positioned to one side of each of the major stator electromagnets on a centreline 13.5 degrees from the centreline of the stator magnet, and these are excited in a predetermined pattern or sequence. Similarly, to one side of each rotor electromagnet, is a second electromagnet spaced on a 13.5 degree centreline from the major rotor electromagnet. Electromagnets in both the rotor and stator assemblies are identical, the individual electromagnets of each being aligned axially and the coils of each being wired so that each rotor electromagnetic pole will have the same magnetic polarity as the electromagnet in the stator with which it is aligned and which it is confronting at the time of discharge of the capacitor.

Charging of the discharge capacitor or capacitors is accomplished by an electrical switching circuit wherein electrical energy from a battery or other source of d-c potential is derived through rectification by diodes.

The capacitor charging circuit comprises a pair of high frequency switchers which feed respective automotive-type ignition coils employed as step-up transformers. The "secondary" of each of the ignition coils provides a high voltage square wave to a half-wave rectifier to generate a high voltage output pulse of d-c energy with each switching alternation of the high frequency switcher. Only one polarity is used so that a unidirectional pulse is applied to the capacitor bank being charged.

Successive unidirectional pulses are accumulated on the capacitor or capacitor bank until discharged. Discharge of the bank of capacitors occurs across a spark gap by arc-over. The gap spacing determines the voltage at which discharge or arc-over occurs. An array of gaps is created by fixed elements in the engine housing and moving elements positioned on the rotor shaft. At the instant when the moving gap elements are positioned

opposite fixed elements during the rotor rotation, a discharge occurs through the coils of the aligned rotor and stator electromagnets to produce the repulsion action between the stator and rotor electromagnet cores.

A plurality of fixed gap elements are arrayed in a motor housing to correspond to the locations of the stator electromagnets in the housing. The rotor gap elements correspond to the positions of the rotor electromagnets on the rotor so that at the instant of correct alignment of the gaps, the capacitors are discharged to produce the necessary current through the stator and rotor coils to cause the electromagnets to repel one another.

The charging circuits are arranged in pairs, and are such that the discharge occurs through both rotor and stator windings of the electromagnets, which are opposite one another when the spark gap elements are aligned and arc-over.

The speed of the rotor can be changed by means of a clutch mechanism associated with the rotor. The clutch shifts the position of the rotor gap elements so that the discharge will energise the stator coils in a manner to advance or retard the time of discharge with respect to the normal rotor/stator alignment positions. The discharge through the rotor and stator then occurs when the rotor has passed the stator by 6.66 degrees for speed advance.

By causing the discharge to occur when the rotor position is approaching the stator, the repulsion pulse occurs 6.66 degrees before the alignment position of the rotor and stator electromagnets, thus reducing the engine speed.

The clutch mechanism for aligning capacitor discharge gaps for discharge is described as a control head. It may be likened to a firing control mechanism in an internal combustion engine in that it "fires" the electromagnets and provides a return of any discharge overshoot potential back to the battery or other energy source.

The action of the control head is extremely fast. From the foregoing description, it can be anticipated that an increase in speed or a decrease in speed of rotation can occur within the period in which the rotor electromagnet moves between any pair of adjacent electromagnets in the stator assembly. These are 40 degrees apart so speed changes can be effected in a maximum of one-ninth of a revolution.

The rotor speed-changing action of the control head and its structure are believed to be further novel features of the invention, in that they maintain normal 120 degree firing positions during uniform speed of rotation conditions, but shift to 6.66 degree longer or shorter intervals for speed change by the novel shift mechanism in the rotor clutch assembly.

Accordingly, the preferred embodiment of this invention is an electric rotary engine wherein motor torque is developed by discharge of high potential from a bank of capacitors, through stator and rotor electromagnet coils when the electromagnets are in alignment. The capacitors are charged from batteries by a switching mechanism, and are discharged across spark gaps set to achieve the discharge of the capacitor charge voltage through the electromagnet coils when the gaps and predetermined rotor and stator electromagnet pairs are in alignment.

Exemplary embodiments of the invention are herein illustrated and described. These exemplary illustrations and description should not be construed as limiting the invention to the embodiments shown, because those skilled in the arts appertaining to the invention may conceive of other embodiments in the light of the description within the ambit of the appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS:

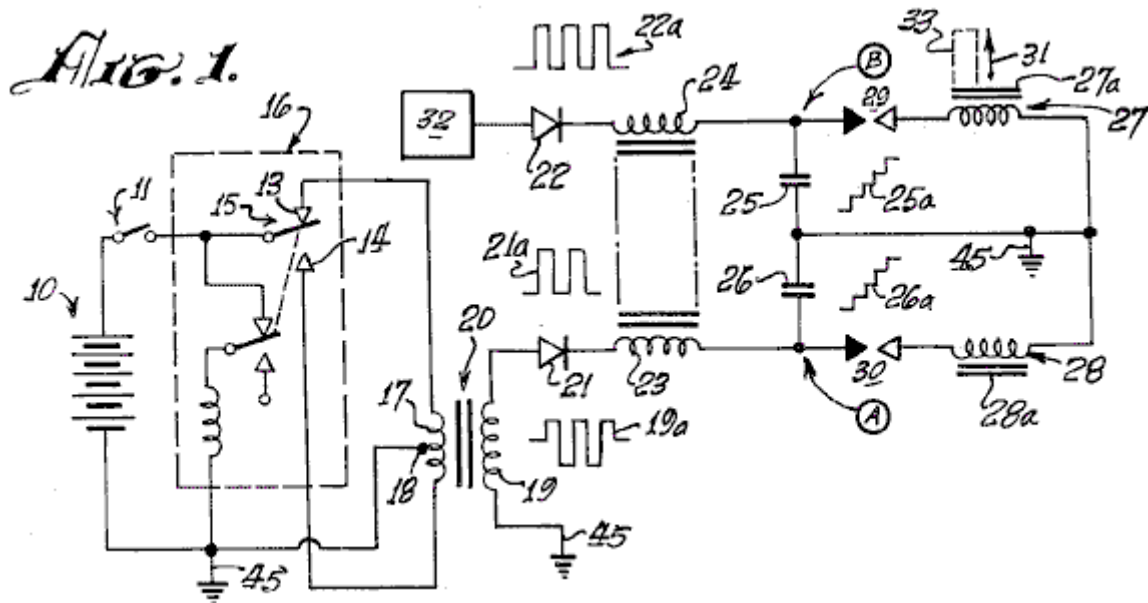

Fig.1 is an explanatory schematic diagram of a capacitor charging and discharging circuit utilised in the present invention.

Fig.2 is a block diagram of an exemplary engine system according to the invention.

Fig.3 is a perspective view of a typical engine system according to the invention, coupled to an automotive transmission.

Fig.4 is an axial sectional view taken at line 4---4 in Fig.3

Fig. 5 is a sectional view taken at line 5---5 in Fig. 4

Fig. 6 and **Fig. 7** are fragmentary sectional views, corresponding to a portion of Fig. 5, illustrating successive advanced positions of the engine rotor therein.

Fig.8 is an exploded perspective view of the rotor and stator of the engine of Fig.3 and Fig.4

Fig.9 is a cross-sectional view taken at line 9---9 of Fig.4

Fig.10 is a partial sectional view, similar to the view of Fig.9, illustrating a different configuration of electromagnets in another engine embodiment of the invention.

Fig.12 is a sectional view, taken at line 12---12 in Fig.11, showing a clutch plate utilised in the speed change control system of Fig.11

Fig.13 is a fragmentary view, taken at line 13---13 in Fig.12

Fig.14 is a sectional view, taken at line 14---14 in Fig.11, showing a clutch plate which co-operates with the clutch plate of Fig.12

Fig.15 is a fragmentary sectional view taken at line 15---15 of Fig.13

Fig.16 is a perspective view of electromagnets utilised in the present invention.

Fig.17 is a schematic diagram showing co-operating mechanical and electrical features of the programmer portion of the invention.

Fig.18 is an electrical schematic diagram of an engine according to the invention, showing the electrical relationships of the electromagnetic components embodying a new principle of the invention, and

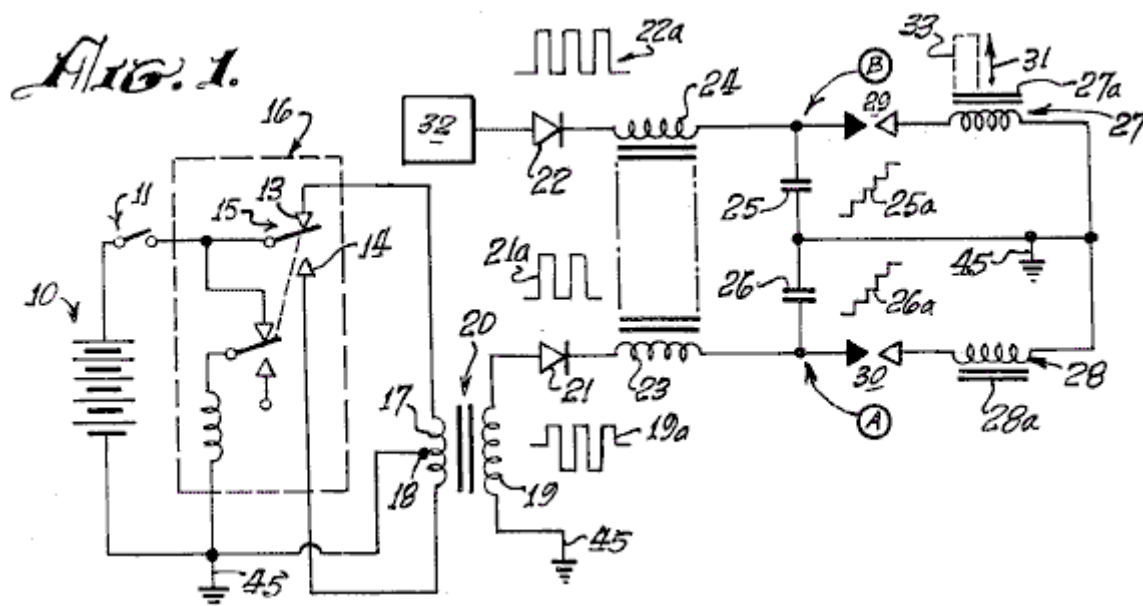

Fig.19 is a developed view, taken at line 19---19 of Fig.11, showing the locations of displaced spark gap elements of the speed changing mechanism of an engine according to the invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

As mentioned earlier, the basic principle of operation of the engine of the invention, is the discharge of a capacitor across a spark gap and through an inductor. When a pair of inductors is used, and the respective magnetic cores thereof are arranged opposite one another and arranged in opposing magnetic polarity, the discharge through them causes the cores to repel each other with considerable force.

Referring to the electrical schematic diagram of **Fig.1**, a battery **10** energises a pulse-producing vibrator mechanism **16**, which may be of the magnetic type, incorporating an armature **15** moving between contacts **13** and **14**, or of the transistor type (not shown) with which a high frequency bipolar pulsed output is produced in primary **17** of transformer **20**. The pulse amplitude is stepped up in secondary **19** of transformer **20**. Wave form **19a** represents the bi-directional or bi-polar pulsed output. A diode rectifier **21** produces a unidirectional pulse train, as indicated at **21a**, to charge capacitor **26**. Successive unidirectional pulses of wave **21a** charge capacitor **26** to high level, as indicated at **26a**, until the voltage at point **A** rises high enough to cause a spark across the spark gap **30**. Capacitor **26** discharges via the spark gap, through the electromagnet coil **28**. A current pulse is produced which magnetises core **28a**. Simultaneously, another substantially identical charging system **32** produces a discharge through inductor **27** across spark gap **29**, to magnetise core **27a**. Cores **27a** and **28a** are wound with coils **27** and **28** respectively, so that their magnetic polarities are the same. As the cores **27a** and **28a** confront one another, they tend to fly apart when the discharge occurs through coils **27** and **28** because of repulsion of identical magnetic poles, as indicated by arrow **31**. If core **28a** is fixed or stationary, and core **27a** is moveable, then core **27a** may have tools **33** attached to it to perform work when the capacitor discharges.

Referring to **Fig.1** and **Fig.2**, a d-c electrical source or battery **10**, energises pulsators **36** (including at least two vibrators **16** as previously described) when switch **11** between the battery **10** and pulsator **36** is closed, to apply

relatively high frequency pulses to the primaries of transformers **20**. The secondaries of transformers **20** are step-up windings which apply bipolar pulses, such as pulses **19a** (Fig.1) to the diodes in converter **38**. The rectified unidirectional pulsating output of each of the diodes in converter **38** is passed through delay coils **23** and **24**, thus forming a harness **37**, wound about the case of the engine, as herein after described, which is believed to provide a static floating flux field. The outputs from delay lines **37**, drive respective capacitors in banks **39**, to charge the capacitors therein, to a relatively high charge potential. A programmer and rotor and stator magnet control array **40, 41, 42**, is formed by spark gaps positioned, as hereinafter described, so that at predetermined positions of the rotor during rotation of the engine, as hereinafter described, selected capacitors of the capacitor banks **39** will discharge across the spark gaps through the rotor and stator electromagnets **43** and **44**. The converters **38**, programmer **40**, and controls **41** and **42**, form a series circuit path across the secondaries of transformers **20** to the ground, or point of reference potential, **45**. The capacitor banks **39** are discharged across the spark gaps of programmer **40** (the rotor and stator magnet controls **41** and **42**). The discharge occurs through the coils of stator and rotor electromagnets **43** and **44** to ground **45**. Stator and rotor electromagnets are similar to those shown at **27, 27a, 28** and **28a** in Fig.1.

The discharge through the coils of stator and rotor electromagnets **43** and **44** is accompanied by a discharge overshoot or return pulse, which is applied to a secondary battery **10a** to store this excess energy. The overshoot pulse returns to battery **10a** because, after discharge, the only path open to it is that to the battery **10a**, since the gaps in **40, 41** and **42** have broken down, because the capacitors in banks **39** are discharged and have not yet recovered the high voltage charge from the high frequency pulsers **36** and the converter rectifier units **38**.

In the event of a misfire in the programmer control circuits **40, 41** and **42**, the capacitors are discharged through a rotor safety discharge circuit **46** and returned to batteries **10-10a**, adding to their capacity. The circuit **46** is connected between the capacitor banks **39** and batteries **10, 10a**.

Referring to Fig.3, a motor or engine **49** according to the present invention is shown connected with an automotive transmission **48**. The transmission **48**, represents one of many forms of loads to which the engine may be applied. A motor housing **50**, encases the operating mechanism hereinafter described. The programmer **40** is axially mounted at one end of the housing. Through apertures **51** and **52**, a belt **53** couples to a pulley **57** (not shown in this view) and to an alternator **54** attached to housing **50**. A pulley **55** on the alternator, has two grooves, one for belt **53** to the drive pulley **58** on the shaft (not shown) of the engine **49**, and the other for a belt **58** coupled to a pulley **59** on a pump **60** attached to housing **50**. A terminal box **61** on the housing, interconnects between the battery assembly **62** and motor **49** via cables **63** and **64**.

An intake **65** for air, is coupled to pump **60** via piping **68** and **69** and from pump **60** via tubing or piping **66** and **70** to the interior of housing **50** via coupling flanges **67** and **71**. The air flow tends to cool the engine and the air may preferably be maintained at a constant temperature and humidity so that a constant spark gap discharge condition is maintained. A clutch mechanism **80** is provided on programmer **40**.

Referring to **Fig.4**, **Fig.5** and **Fig.9**, rotor 81 has spider assemblies 83 and 84 with three electromagnet coil assembly sets mounted thereon, two of which are shown in **Fig.4**, on 85, at 85a and 85b and on 86 at 86a and 86b. One of the third electromagnet coil assemblies, designated 87a, is shown in **Fig.5**, viewed from the shaft end. As more clearly shown in the perspective view of **Fig.8**, a third spider assembly 88 provides added rigidity and a central support for the rotor mechanism on shaft 81.

The electromagnet sets 85a, 85b, 86a, 86b, 87a and 87b, disposed on rotor 81 and spiders 83, 84 and 88, each comprise pairs of front units 85a, 86a and 87a and pairs of rear units 85b, 86b and 87b. Each pair consists of a major electromagnet and a minor electromagnet, as hereinafter described, which are imbedded in an insulating

material **90**, which insulates the electromagnet coil assemblies from one another and secures the electromagnets rigidly in place on the spider/rotor cage **81, 83, 84** and **88**.

The interior wall **98**, of housing **50**, is coated with an electrically insulating material **99** in which are imbedded electromagnet coils, as hereinafter described, and the interiors of end plates **100** and **101** of the housing **50**. On the insulating surface **98** of housing **50** is mounted a series of stator electromagnet pairs **104a**, identical with electromagnet pairs **85a, 86a, 87a**, etc. Electromagnet pairs such as **104a** or **105a** are disposed every **40** degrees about the interior of housing **50** to form a stator which co-operates with the rotor **81-88**. An air gap **110** of very close tolerance is defined between the rotor and stator electromagnets and air from pump **65** flows through this gap.

As shown in **Fig.8**, the electromagnet assemblies, such as **85** through **87**, of the rotor and magnet assemblies, such as **104a** in the stator, are so embedded in their respective insulating plastic carriers (rotor and stator) that they are smoothly rounded in a concave contour on the rotor to permit smooth and continuous rotation of rotor **81** in stator housing **50**. The air gap **110** is uniform at all positions of any rotor element within the stator assembly, as is clearly shown in **Fig.16**.

The rotor **81** and spiders **83, 84** and **88** are rigidly mounted on shaft **111** journaled in bearing assemblies **112** and **113** which are of conventional type, for easy rotation of the rotor shaft **111** within housing **50**.

Around the central outer surface of housing **50**, are wound a number of turns of wire **23** and **24** to provide a static flux coil **114** which is a delay line, as previously described. **Figs. 5, 6, 7** and **9** are cross-sectional views of the rotor assembly **81-88**, arranged to show the positioning and alignment of the rotor and stator electromagnet coil assemblies at successive stages of the rotation of the rotor **81-88** through a portion of a cycle of operation thereof. For example, in **Fig.5** the rotor assembly **81-88** is shown so positioned that a minor rotor electromagnet assembly **91** is aligned with a minor stator electromagnet assembly **117**.

As shown in further detail in **Fig.16**, minor electromagnet assembly **117** consists of an iron core **118**, grooved so that a coil of wire **119** may be wound around it. Core **118** is the same in stator electromagnet **117** as it is in rotor electromagnet **91**.

As a position **13.33** degrees to the right of rotor electromagnet **91**, as viewed in **Fig.5** and **Fig.16**, there is a second or major rotor electromagnet **121** which has a winding **123** about its core **122**. The electromagnets **91** and **121** are the pair **85a** of **Fig.4** and **Fig.8**.

At a position 13.33 degrees to the left of stator electromagnet **117**, as viewed in **Fig.5**, there is a second or major stator electromagnet **120** whose core **122** is of the same configuration as core **122** of rotor electromagnet **121**. A winding **123** about core **122** of electromagnet **120** is of the same character as winding **123** on electromagnet **121**.

Electromagnet assembly pair **85a** on the rotor is identical in configuration to that of the electromagnet stator assembly pair **104a** except for the position reversal of the elements **117-120** and **91-121** of the respective pairs.

There are none pairs of electromagnets **120-117** (**104a**) located at 40 degree intervals about the interior of housing **50**. The centreline of core **122** of electromagnet **120** is positioned 13.33 degrees to the left of the centreline of the core **118** of electromagnet **117**. Three pairs of electromagnets **85a**, **86a** and **87a** are provided on rotor assembly **81-88** as shown in **Fig.5**.

Other combinations are possible, but the number of electromagnets in the rotor should always be in integral fraction of the number of electromagnets in the stator. As shown in **Fig.8**, for the rotor assembly **85a** and **85b**, there are three of each of the front and back pairs of electromagnetic assemblies. Similarly, as shown in **Fig.4** and **Fig.8**, there are nine front and back pairs of electromagnets in the stator such as **104a** and **104b**.

In order to best understand the operation of the rotor **81-88** rotating within the stator housing **50** of an engine according to this invention, the positions of rotor electromagnets **91** and stator electromagnets **117** are initially exactly in line at the 13.33 degree peripheral starting position marked on the vertical centreline of **Fig.5**. The winding direction of the coils of these magnets is such that a d-c current through the coils **119** will produce a particular identical magnet polarity on each of the juxtaposed surfaces **125** of magnet **117** and **126** of magnet **91** (**Fig.5**). **Fig.16** and **Fig.6** illustrate the next step in the motion wherein the two major electromagnets, **120** in the stator and **121** in the rotor, are in alignment.

When the d-c discharges from the appropriate capacitors in banks **39** occur simultaneously across spark gaps through the coils **119** of electromagnets **117** and **91**, at the instant of their alignment, their cores **118**, will repel one another to cause rotor assembly **81-88** to rotate clockwise in the direction indicated by arrow **127**. The system does not move in the reverse direction because it has been started in the clockwise direction by the alternator motor **54** shown in **Fig.3**, or by some other starter means. If started counterclockwise, the motor will continue to rotate counterclockwise.

As noted earlier, the discharge of any capacitor occurs over a very short interval via its associated spark gap and the resulting magnetic repulsion action imparts motion to the rotor. The discharge event occurs when electromagnets **117** and **91** are in alignment. As shown in **Fig.5**, rotor electromagnet **91a** is aligned with stator electromagnet **117c**, and rotor electromagnet **91b** is aligned with stator electromagnet **117e** at the same time that similar electromagnets **117** and **91** are aligned. A discharge occurs through all six of these electromagnets simultaneously (that is, **117**, **91**, **117c**, **91a**, **117e** and **91b**). A capacitor and a spark gap are required for each coil of each electromagnet. Where, as in the assembly shown in **Fig.8**, front and back pairs are used, both the axial in-line front and back coils are energised simultaneously by the discharge from a single capacitor or from a bank of paralleled capacitors such as **25** and **26** (**Fig.1**). Although **Fig.4** and **Fig.8** indicate the use of front and back electromagnets, it should be evident that only a single electromagnet in any stator position and a corresponding single electromagnet in the rotor position, may be utilised to accomplish the repulsion action of the rotor with respect to the stator. As stated, each electromagnet requires a discharge from a single capacitor or

capacitor bank across a spark gap for it to be energised, and the magnetic polarity of the juxtaposed magnetic core faces must be the same, in order to effect the repulsive action required to produce the rotary motion.

Referring to **Fig.5** and **Fig.6**, the repulsion action causes the rotor to move 13.33 degrees clockwise, while electromagnets **91**, **91a** and **91b** move away from electromagnets **117**, **117c** and **117e** to bring electromagnets **121**, **121a** and **121b** into respective alignment with electromagnets **120a**, **120d** and **120f**. At this time, a capacitor discharge across a spark-gap into their coils **123** occurs, thus moving the rotor. Another 13.33 degrees ahead, as shown in **Fig.7**, major electromagnets **121**, **121a** and **121b** come into alignment with minor electromagnets **117a**, **117d** and **117f**, at which time a discharge occurs to repeat the repulsion action, this action continuing as long as d-c power is applied to the system to charge the capacitor banks.

Fig.18 further illustrates the sequencing of the capacitor discharges across appropriate spark gap terminal pairs. Nine single stator coils and three single rotor coils are shown with their respective interconnections with the spark gaps and capacitors with which they are associated for discharge. When the appropriate spark gap terminals are aligned, at the points in the positioning of the rotor assembly for most effective repulsion action of juxtaposed electromagnet cores, the discharge of the appropriate charged capacitors across the associated spark gap occurs through the respective coils. The capacitors are discharged in sets of three, through sets of three coils at each discharge position, as the rotor moves through the rotor positions. In **Fig.18**, the rotor electromagnets are positioned linearly, rather than on a circular base, to show the electrical action of an electric engine according to the invention. These motor electromagnets **201**, **202** and **203** are aligned with stator electromagnets **213**, **214** and **215** at 0 degrees, 120 degrees and 240 degrees respectively. The stator electromagnets are correspondingly shown in a linear schematic as if rolled out of the stator assembly and laid side by side. For clarity of description, the capacitors associated with the rotor operation **207**, **208**, **209** and **246**, **247**, **248**, **249**, **282** and **283**, are arranged in vertical alignment with the respective positions of the rotor coils **201**, **202** and **203** as they move from left to right, this corresponding to clockwise rotation of the rotor. The stator coils **213**, **214**, **215**, **260**, **261**, **262**, **263**, **264**, **265**, **266**, etc. and capacitor combinations are arranged side by side, again to facilitate description.

An insulative disc **236** (shown in **Fig.17** as a disc but opened out linearly in **Fig.18**) has mounted thereon, three gap terminal blocks **222**, **225** and **228**. Each block is rectangularly U-shaped, and each interconnects two terminals with the base of the U. Block **222** has terminals **222a** and **222b**. Block **225** has terminals **225a** and **225b**. Block **228** has terminals **228c** and **228d**. When insulative disc **230** is part of the rotor as indicated by mechanical linkage **290**, it can be seen that terminal U **222** creates a pair of gaps with gap terminals **223** and **224** respectively. Thus, when the voltage on capacitor **216** from charging unit **219**, is of a value which will arc over the air spaces between **222a** and **223**, and between **222b** and **224**, the capacitor **216** will discharge through the coil of electromagnet **213** to ground. Similarly, gap terminal U **225** forms a dual spark gap with gap terminals **226** and **227** to result in arc-over when the voltage on capacitor **217**, charged by charging circuit **220**, discharges into the coil of electromagnet **214**. Also, U-gap terminal **228** with terminals **228c** and **228d**, creates a spark gap with terminals **229** and **230** to discharge capacitor **218**, charged by charging circuit **221**, into coil **215**. At the same time, rotor coils, **201**, **202** and **203** across gaps **201a - 204**, **202b - 205** and **203c - 206** each receives a discharge from respective capacitors **207**, **208** and **209**.

When the electromagnet coils **213**, **214** and **215** and **201**, **202** and **203** are energised, the repulsion action causes the rotor assembly to move to position 2 where a new simultaneous group of discharges occurs into rotor coils **201**, **202** and **203** from capacitors **246**, **248** and **282** across gaps **201a - 240**, **202b - 242** and **203c - 244**. Simultaneously, because gap-U-elements **222**, **225** and **228** have also moved to position 2 with the rotor assembly, capacitor **261** is discharged through electromagnet coil **260**, capacitor **265** is discharged through electromagnet coil **264**, and capacitor **269** is discharged through electromagnet coil **268** in alignment with position 2 of the rotor electromagnet coils, thus to cause the rotor electromagnets to move to position 3 where the discharge pattern is repeated now with capacitors **247**, **249** and **283** discharging through the rotor electromagnet coils **201**, **202** and **203**, and the capacitors **263**, **267** and **281** discharging respectively through stator electromagnet coils **262**, **266** and **280**.

After each discharge, the charging circuits **219 - 221** and **272 - 277** for the stator capacitors, and **210 - 212** and **284 - 289** for the rotor capacitors, are operated continuously from a battery source as described earlier with reference to **Fig.1**, to constantly recharge the capacitors to which each is connected. Those versed in the art will appreciate that, as each capacitor discharges across an associated spark gap, the resulting drop in potential across the gap renders the gap an open circuit until such time as the capacitor can recharge to the arc-over level for the gap. This recharge occurs before a rotor element arrives at the next position in the rotation.

The mechanical schematic diagram of **Fig.17**, further clarifies the operation of the spark-gap discharge programming system. A forward disc **236** of an electrically insulative material, has thereon the set of U-shaped gap terminal connectors previously described. These are positioned at 0 degrees, 120 degrees and 240 degrees respectively. In **Fig.17**, schematic representations of the position of the coil and capacitor arrangements at the

start of a cycle are shown to correspond to the above description with reference to **Fig.18**. Accordingly, the coil and capacitor combinations **213/216**, **214/217** and **215/218** are shown connected with their gap terminals, respectively, **223/224**, **226/227** and **229/230**. On the rotor coil and capacitor connection, three separate discs **291**, **292** and **293** are shown, each with a single gap terminal. The discs **291 - 293** are rotated so as to position their respective gap terminals 201a, 201b and 201c, at 120 degree increments, with the 0 degrees position corresponding to the 0 degrees position of U-gap terminal **222** on disc **230**.

Representative gap terminals are shown about the peripheries of discs **230**, **291 - 293** to indicate clearly how, as the discs turn in unison, the gap alignments correspond so that three rotor coils always line up with three stator coils at 120 degree intervals about the rotary path, producing an alignment every 40 degrees, there being nine stator coils. Thus, there are three simultaneous discharges into stator coils and three into rotor coils at each 40 degree position. Nine positions displaced 40 degrees apart provide a total of 27 discharge points for capacitors into the rotor coils and 27 discharge points for capacitors into the stator coils in one revolution of the rotor.

It will be understood that, as illustrated in **Fig.17** and **Fig.18**, nine individual electromagnet coils are shown in the stator and three in the rotor, in order to show in its simplest form, how the three rotor electromagnets are stepped forward from alignment with three of the stator electromagnets, when the appropriate spark gaps are in alignment, to effect the discharge of capacitors through juxtaposed pairs of rotor/stator electromagnets. The repulsion moves the rotor electromagnet from the stator electromagnet to the next alignment position 40 degrees further on. In the interval, until another rotor electromagnet, 120 degrees removed, is aligned with the stator electromagnet which had just been pulsed, the associated capacitor is recharged. Thus, the rotor moves from one position to the next, with capacitor discharges occurring each 40 degrees of rotation, a total of nine per revolution. It should be obvious that, with other rotor/stator combinations, the number of electromagnet coincidences and spark-gap discharges will vary. For example, with the coil pairs shown in **Figs 4 through 8**, a total of 27 discharges will occur. Although there are 18 stator electromagnets and 3 rotor electromagnets, the discharge pattern is determined by the specific spark gap arrangement.

The rotor/stator configuration of **Fig.5** and **Fig.8**, involving the major and minor pairs of electromagnets, such as **85a** and **104a** (the terms "minor" and "major" referring to the difference in size of the elements), include nine pairs of electromagnets in the stator, such as **104a**, with three electromagnet pairs of the rotor, such as **85a**. Because of the 13.33 degree separation between the major and minor electromagnets in the rotor pair **85a**, with the same separation of minor and major electromagnets of the stator pair **104a**, the sequence of rotation and discharge described above, with respect to the illustrative example of **Fig.5**, involves the following:

1. A minor element **117** of stator pair **104a** is aligned with the minor element **91** of rotor pair **85a**. On the discharge, this moves the rotor ahead 13.33 degrees.
2. the major rotor element **122** of the pair **85a**, now is aligned with the major stator element **120b** of the next stator electromagnet pair, in the stator array as shown in **Fig.6**. On the discharge, the rotor moves ahead 13.33 degrees.
3. This brings the minor rotor electromagnet **91** into alignment with the major stator electromagnet **120b** of pair **104d**, and the major electromagnet **122** (just discharged) of pair **85a** into alignment with minor electromagnet **117b** of pair **104d**, and the rotor spark gap elements into alignment with a different position of gap elements connected with capacitors not discharged in the previous position of the rotor. It should be remembered at this point that it is the positioning of a rotatable spark gap array, similar to that illustrated in **Fig.17** and **Fig.18**, which controls the time of discharge of capacitors connected to these gap terminals. Therefore, any electromagnet can be energised twice, successively, from separate capacitors as the rotor brings appropriate gap terminals into alignment with the coil terminals of a particular electromagnet.

Thus, although major electromagnet **120b** of pair **104d** has just been energised as described above, it can now be energised again along with minor rotor electromagnet **91** in step 3, because the rotor moved to a new set of terminals of the spark gap arrays connected to capacitors which have not yet been discharged. These capacitors now discharge through rotor electromagnet **91** and stator electromagnet **120b**, causing the rotor to move ahead another 13.33 degrees, thus again aligning two minor electromagnets again, these being **117b** of stator pair **104d** and **91** of rotor pair **85a**. The rotor has now moved 40 degrees since step 1 above. The sequence is now repeated indefinitely. It is to be noted that at each 13.33 degree step, the discharges drive the rotor another 13.33 degrees. There are 27 steps per revolution with nine stator coil pairs. The discharge sequence is not uniform, as is shown in Table 1. In the stator, three major electromagnets 120 degrees apart are energised twice in sequence, followed by a hiatus of one step while three minor electromagnets of the stator, 120 degrees apart, are energised during the hiatus. In the rotor the major electromagnets are energised during a hiatus step following two minor electromagnet energisation steps. A total of 27 energisations are this accomplished in the nine pairs of coils of the stator.

In Table 1, the leftmost column shows the location of each rotor arm **85**, **86** and **87** at an arbitrarily selected step No. 1 position. For example, in step 1, rotor arm **85** has a minor stator and minor rotor electromagnet in alignment for capacitors to discharge through them simultaneously at the 13.33 degree position.

TABLE I

CAPACITOR DISCHARGE SEQUENCE FOR ONE REVOLUTION OF ROTOR IN SYSTEM OF FIGS. 5 AND 8							
Step No.	Rotor Arm		Rotor Angle	Rotor Electro- magnet		Stator Electro- magnet	
	87	85	86	Minor	Major	Minor	Major
10	1	19	13 1/3°	x		x	
11	2	20	26 2/3°		x		x
12	3	21	40°	x			x
13	4	22	53 1/3°	x		x	
14	5	23	66 2/3°		x		x
15	6	24	80°	x			x
16	7	25	93 1/3°	x		x	
17	8	26	106 2/3°		x		x
18	9	27	120°	x			x
19	10	1	133 1/3°	x		x	
20	11	2	146 2/3°		x		x
21	12	3	160°	x			x
22	13	4	173 1/3°	x		x	
23	14	5	186 2/3°		x		x
24	15	6	200°	x			x
25	16	7	213 1/3°	x		x	
26	17	8	226 2/3°		x		x
27	18	9	240°	x			x
1	19	10	253 1/3°	x		x	
2	20	11	266 2/3°		x		x
3	21	12	280°	x			x
4	22	13	293 1/3°	x		x	
5	23	14	306 2/3°		x		x
6	24	15	320°	x			x
7	25	16	333 1/3°	x		x	
8	26	17	346 2/3°		x		x
9	27	18	360°	x			x

Similarly, in step 1, rotor arm **86** is at the 133.33 degree position which has two minor electromagnets in alignment, ready for discharge. Simultaneously, rotor arm 87 is at the 253.33 degree position with two minor electromagnets aligned for capacitor discharge. The other steps of the sequence are apparent from Table 1, for each position of the three rotor arms at any step and the juxtapositions of respective stator and rotor electromagnet elements at that position.

In the simplified motor arrangement shown in schematic form in **Fig.18**, with single electromagnet configuration, the alignment is uniform and the discharge sequences follow sequentially.

As mentioned before, a change in speed is effected by displacing the stator spark gap terminals on the rotor (shown at **236** in **Fig.17** and **Fig.18**) either counterclockwise or clockwise 6.66 degrees so that the discharge position of the stator electromagnets is displaced. Referring to **Figs. 11 to 15**, the simultaneous discharge of selected capacitors into the displaced electromagnets results in a deceleration if the rotor electromagnet is approaching the stator electromagnet at the time of discharge, or an acceleration if the rotor electromagnet is leaving the stator electromagnet at the time of the discharge pulse. In each event, there is a repulsive reaction between the stator and rotor electromagnets which effects this change in speed.

Referring to **Fig.11**, clutch mechanism **304** about shaft **111** is operated electromagnetically in conventional manner, to displace the spark-gap mechanism **236** which is operated normally in appropriate matching alignment with the rotor spark-gap discs **291**, **292** and **293**. Clutch **304** has a fixed drive element **311**, containing an electromagnetic drive coil (not shown) and a motor element **310** which, when the electromagnetic drive coil is energised, can be operated by a direct current. The operation of motor element 310, brings into operation, spark gap elements **224r**, **223r** or **223f**, **224f** of the system shown in **Figs. 4, 5 and 8**, as illustrated in **Fig.19**.

The fixed stator coil spark gap terminal pairs **223**, **224** and **266**, **267** are arrayed about a cylindrical frame **322** which is fabricated in insulative material. In the illustrative example of **Fig.17** and **Fig.18**, there are nine such spark gap terminal pairs positioned around the periphery of the cylinder frame **324**. In the engine of **Figs. 4 to 8**, a total of 27 such spark gap pairs are involved. In addition, although not shown in the drawing, there are also pairs of terminals, such as **223r** or **223f**, **224r** or **224f** and **226r** or **226f**, **267r** or **267f**, displaced 6.66 degrees on either side of the pairs **223**, **224** or **266**, **267** and all other pairs in the spark gap array, the letters "r" and "f" denoting "retard" or "faster". The latter displaced pairs are used in controlling the speed of the engine rotor. The displaced pairs not shown are involved in the operation of the clutch **304**, the speed-changing control element.

Clutch **304** is associated with shaft **111** in that the movable element **310** draws clutch disc element **316** on shaft **111**, away from clutch disc element **322** when energised by a voltage of appropriate polarity applied to its motor electromagnet **311**. Such clutch drives are well known in the art.

The clutch mechanism **304** of **Fig.11** and **Fig.19**, when not energised, is in the configuration shown in **Fig.11**. The energised configuration of clutch **304** is not specifically illustrated. Upon energisation, spark-gap element **222** on disc **236** is displaced rightward, as viewed in **Fig.11**, by broken lines **236X**, into alignment with the positions of fixed spark-gap terminals **223f**, **224f** and **267r**, **266r**. When the disc is in position **236X**, the flattened edge **332** of pin **330** in disc **325** rides on surface **350** of disc **322**. Normally, the flattened edges **351** of pins **330** are engaged against the flat edge **352** in recess **331** of disc **322**. The displacement of disc **322** on shaft **111** is effected by the action of clutch **304** against spring **314** (**Fig.11**). An electric switch (not shown) of clutch mechanism **304** energises it from a d-c power source, and has two positions, one for deceleration and one for acceleration. In either position, clutch **304** is engaged to pull clutch disc **322** from clutch disc **325**, momentarily. For the decelerate or the accelerate position, the displaced alignment of spark gap elements **222** is with the **224f**, **223f** and the **224r**, **223r** spark-gap terminal elements. However, only the **224f**, **223f** spark-gap elements are switched into operation with appropriate capacitors for the accelerate position, while in the decelerate position, only the **223r** and **224r** spark-gap elements are switched into the circuit with their associated capacitors.

Of course, when insulative disc **236** is displaced by clutch **304**, its gap terminals **222**, **225** and **228** (**Fig.14** and **Fig.18**) are all displaced into the alignment position of **236X** so as to engage the "r" and "f" lines of fixed spark gap elements. Although the accelerate and decelerate positions of disc **236** are the same, it is the switching into operation of the **223**, **224** or **266**, **267** exemplary "r" or "f" pairs of terminals which determines whether the rotor will speed up or slow down.

The momentary displacement of clutch disc **322** from clutch disc **325** results in rotation of disc **325** about disc **322** through an angle of 120 degrees. The detent ball and spring mechanism **320**, **321** in disc **325**, positions itself between one detent dimple **328** and a succeeding one **328** at a position 120 degrees away on disc **325**.

As stated, flat **332** of pin **330** rides on surface **350** of disc **322**, and pin **330** leaves the pin-holding groove **331/352** along ramp **333** in disc **322** during the momentary lifting of disc **322** by clutch **304**. Pin **330** falls back into the next groove **331** at a point 120 degrees further on about disc **322**. Pin **330** falls into place in groove **331** on ramp **334**. Pins **330** are rotatable in their sockets **353**, so that for either clockwise or counterclockwise rotation, the flat **351** will engage the flat **352** by the particular ramp it encounters.

The deceleration or acceleration due to the action of clutch **304** thus occurs within a 120 degree interval of rotation of disc **325**. During this interval, disc **322** may only move a fraction of this arc.

There has been described earlier, an electromotive engine system wherein at least one electromagnet is in a fixed position and a second electromagnet of similar configuration is juxtaposed with it in a magnetic polarity relationship such that, when the cores of the electromagnets are energised, the juxtaposed core faces repel each other. One core being fixed, and the second core being free to move, any attachments to the second electromagnet core will move with it. Hence, if a plurality of fixed cores are positioned about a circular confining housing, and, within the housing, cores on a shaft are free to move, the shaft is urged rotationally each time the juxtaposed fixed and rotatable cores are in alignment and energised. Both the fixed and the movable cores are connected to spark gap terminal elements and the associated other terminal elements of the spark gaps are connected to capacitors which are charged to high voltage from pulsed unipolar signal generators. These capacitors are discharged through the electromagnets across the spark gaps. By switching selected groups of capacitors into selected pairs of spark gap elements for discharge through the electromagnets, the rotor of the circular array systems is accelerated and decelerated.

By confining a fixed electromagnet array in a linear configuration, with a linearly movable electromagnet to which a working tool is attached, exciting the juxtaposed pairs of electromagnets by capacitor discharge, results in the generation of linear force for such tools as punch presses, or for discharging projectiles with considerable energy.

CLAIMS:

1. An electric engine comprising:

A housing;

An array of electromagnets uniformly spaced in said housing to form a stator;

A rotor cage on a shaft journaled in and rotatable within said stator, said rotor cage having thereon a spaced array of electromagnets similar to said stator electromagnets and in number, comprising an integral fraction of the number of electromagnets in said stator array;

Each of the electromagnets of said stator and of said rotor, having a core which can be magnetised and of a particular configuration and each being wound with a coil such that a pulses of unidirectional electric current through said coil, magnetises the respective core thereof to a particular magnetic polarity, and the faces of rotor cores juxtaposing selected stator cores are magnetised to the same polarity, the juxtaposed cores thereby tending to repel one another, one lead of each of the stator and rotor coils being connected to a common terminal, the other lead of each of said coils being connected to a gap terminal, the gap terminals of said rotor coils being on the rotor and equal in number to the number of coils thereon and matching the positions of said rotor electromagnets thereon, the gap terminals of said stator being equal in number to the number of coils on the stator and disposed uniformly about said stator to match the positions of said stator electromagnets within said housing;

A first array of capacitors, each having a terminal in common with the common coil terminal of said stator electromagnets, and each capacitor having its other terminal connected to a gap terminal arrayed adjacent the gap terminal of an electromagnet associated therewith;

A second array of capacitors, each having a terminal in common with said common terminal of said rotor electromagnet coils but equal in number to the number of capacitors in said stator array, the other terminals of said capacitors in said second array being connected to gap terminals arrayed about said housing so as to be in axial alignment with said stator gap terminal positions and being alignable with said rotor gap terminals as said rotor is rotated in said housing and respective gap terminals of said rotor coils pass each second array capacitor gap terminals at a predetermined gap distance;

Gap coupling terminals on said rotor equal in number to the number of rotor electromagnet coils and positioned to match the rotor electromagnet positions on said rotor, the gap coupling terminals being rotatable with said rotor so as to pass said adjacent stator coil and associated stator capacitor gap terminal at a predetermined distance therefrom;

A plurality of capacitor charging circuits connected respectively across each of said capacitors in both said first and said second arrays of capacitors for charging each of said capacitors to a predetermined high d-c potential;

A first source of unidirectional electric potential connected to each of said capacitor charging circuits for energising said charging circuits; and

A second unidirectional electric potential source connected to said electromagnets of said rotor and said stator of such polarity as to receive a charge from the inverse inductive discharge of the electromagnet coils as their fields collapse following the discharge of each capacitor through a rotor or stator electromagnet coil,

Whereby, whenever a rotor electromagnet is aligned opposite a stator electromagnet, the rotor coil gap terminal of that electromagnet is opposite an associated second capacitor array gap terminal, and a gap coupling terminal of said rotor is aligned opposite the stator electromagnet coil gap terminal and associated first capacitor gap terminal, the capacitors discharge the charge thereon across the gaps through their associated electromagnet coils to magnetise their respective juxtaposed electromagnet cores to cause them to repel one another, thus aligning a succeeding pair of rotor and stator electromagnets for capacitor discharge across their respective gaps, to cause them to repel one another, alignments rotor rotation within the housing continuously bringing successive rotor-stator electromagnets into alignment for discharge of the capacitors through them to produce continuous rotary motion of the rotor on said rotor shaft, so long as energy is applied to said charging circuits to recharge said capacitors after each discharge.

2. In an electric engine having a rotor comprising electromagnetic coil means rotatable within a stator comprising similar electromagnetic coil means, said electromagnetic coil means being polarised for magnetic repulsion;

Capacitor means electrically coupled across successive spark gaps to selected ones of said stator and all of the coils of said rotor;

Charging means connected to said capacitor means for charging said capacitor means to an electrical charge potential sufficient to cause arcing across said spark gaps to result in the discharge of said capacitor means through the electromagnetic coil means repel one another; and

A unidirectional electric power source connected to said charging means to energise said charging means to continue charging said capacitor means following each discharge whereby the rotor of said engine is maintained

in rotation by the successive discharges of said capacitor means across successive spark gaps into said electromagnetic coil means.

3. An electric engine according to claim 2, wherein:

The charging means includes electronic square core oscillators connected to said unidirectional electric power source and includes step-up means and a rectifier to produce a substantial voltage step up from the voltage of said power source.

4. An electric engine according to claim 2, wherein:

The charging means includes a vibrator connected to said power source, and step-up transformer and rectifier means to provide a high voltage for charging said capacitor means.

5. A motive force-producing means comprising:

At least a first electromagnet means including at least one coil wound about a core,

At least a second electromagnet means including at least one coil wound about a core similar to said first core,

The respective cores being positioned adjacent to one another so that the magnetic polarities of the adjacent core surfaces are the same when a unidirectional electric current is passed through the coils,

At least one capacitor means having one terminal thereof connected to one terminal of both of said electromagnet coils,

The other terminal of said capacitor means being connected to one terminal of a spark gap means, the other terminals of the coils of both said first and said second electromagnet means being connected to the other terminal of said spark gap means,

At least one unidirectional pulse charging means connected to said capacitor means to charge said capacitor means to a relatively high potential sufficient to arc across said spark gap means at predetermined spacing of said gap terminals, and

A source of unidirectional potential connected to said charging circuit to energise said charging means,

Whereby upon application of current from said potential source to said charging means the successive pulses generated thereby charge said capacitor means to a voltage level sufficient to arc across said spark gap means to produce a discharge path for said capacitor means through said coils to cause said electromagnet means to repel one another with a substantial force.

6. A motive force-producing means according to claim 5, wherein:

Said first electromagnet means is secured in a relatively stable housing, and said second electromagnet means is connected with and freely movable relative to said stable housing, and has utilisation means connected thereto for performing work therewith when said capacitor means discharges through said coils of said electromagnet means.

7. A motive force-producing means according to claim 6, wherein said utilisation means is a motor rotor coupled with said second electromagnet means and said first electromagnet means is a stator.

8. A motive force-producing means according to claim 6, wherein said utilisation means is a piston attached to said second electromagnet means and is movable therewith to produce hammer-like blows when said capacitor means discharges through said electromagnet means.

9. In an electromotive force-generating system as disclosed, means for accelerating or decelerating the motion of a force-generating system, said means comprising:

At least two juxtaposed electromagnetic core elements, one fixed and one movable, including coils wound around it to provide a repulsion tendency when said cores are energised,

Spark gap terminals connected with said coils,

Capacitor means connected with said spark gap terminals to discharge across said spark gap terminals through said coils when a charge of sufficient voltage level appears across said capacitor means, thus to energise said juxtaposed electromagnets to induce said juxtaposed electromagnet cores to repel one another,

Charging means connected to said capacitors for charging them to said sufficient voltage level, and selective positioning means coupled with said spark gap terminals and with at least said movable electromagnet core to cause selective displacement of said movable core with respect to said fixed core.

10. An electromotive force-generating system according to claim 9, wherein:

Said juxtaposed electromagnetic cores include a plurality of fixed cores and a smaller number of movable cores, said smaller number being an integral fraction of the number of fixed cores, and

Said selective positioning means is an electromagnetic clutch coupled with said smaller number of movable cores for movement therewith, and includes selective displacement means coupled with said spark gap terminals connected with said capacitors in said capacitor means and selected combinations of coils in said plurality of fixed electromagnets.

11. The method of generating motive power comprising the steps of:

a. positioning similar electromagnets in juxtaposed relationship with their respective cores arranged for repulsion when said electromagnets are energised,

b. charging capacitors to a relatively high potential, and

c. discharging said capacitors simultaneously through said electromagnets across spark gaps set to break down at said relatively high potential, thereby to cause said similar electromagnets to repel one another with considerable force.

12. The method of generating motive power defined in claim 11, wherein, in said positioning step at least one of said electromagnets is maintained in a fixed position and another electromagnet is free to move relative to said fixed electromagnet.

13. The method of generating motive power according to claim 11, wherein:

The charging step includes the charging of capacitors to a relatively high potential from a pulsed unipolar source of electrical energy.

14. in an electromagnetic capacitor discharge engine including movable electromagnets and fixed electromagnets, said movable electromagnets being movable into polar alignment with said fixed electromagnets, capacitor means, means for charging said capacitor means, and means for discharging said charged capacitor means through said fixed and movable electromagnets to polarise aligned fixed and movable electromagnets for magnetic repulsion, an acceleration and deceleration control means comprising:

First selective means for momentarily delaying the discharge of the capacitors until the movable electromagnets in said engine have begun to recede from the fixed electromagnets, in order to accelerate the motion of said movable electromagnets by the added impetus of the repulsion, and

Second selective means for momentarily accelerating the discharge of the capacitors to occur at a point in the motion of the movable electromagnets where said movable electromagnets are approaching said fixed electromagnets to decelerate the motion of said movable electromagnets by the tendency to repel the approaching electromagnets by the fixed electromagnets.

15. An electric engine, comprising:

Fixed electromagnets;

Movable electromagnets, movable into alignment with said fixed electromagnets;

Capacitor means;

Means for charging said capacitor means, and

Means for discharging said charged capacitor means through said fixed and movable electromagnets to polarise said aligned fixed and movable electromagnets for magnetic repulsion.

16. An electric engine as recited in claim 15, wherein: said means for discharging said charged capacitor means comprises voltage breakdown switch means.

17. An electric engine as recited in claim 16, wherein:

Said voltage breakdown switch means includes at least one terminal movable with at least one of said movable electromagnets for breaking down when said at least one of said movable electromagnets is in alignment with a said fixed electromagnet.

18. An electric engine as recited in claim 17, wherein:

Said voltage breakdown switch means comprises a spark gap means.

EFFICIENT POWER SUPPLY SUITABLE FOR INDUCTIVE LOADS

Please note that this is a re-worded excerpt from this patent. It describes the circuitry used with Edwin Gray's power tube. Please be aware Edwin wanted at all costs, to conceal any useful technology while getting patents to encourage investors, so please understand that this patent is not intended to tell you how to make a working system of this type.

SUMMARY OF THE INVENTION

The present invention provides a more efficient driving system comprising a source of electrical voltage; a vibrator connected to the low-voltage source for forming a pulsating signal; a transformer connected to the vibrator for receiving the pulsating signal; a high-voltage source, where available, connected to a bridge-type rectifier; or the bridge-type rectifier connected to the high voltage pulse output of the transformer; a capacitor for receiving the voltage pulse output; a conversion element having first and second anodes, electrically conductive means for receiving a charge positioned about the second anode and an output terminal connected to the charge receiving means, the second anode being connected to the capacitor; a commutator connected to the source of electrical voltage and to the first anode; and an inductive load connected to the output terminal whereby a high energy discharge between the first and second anodes is transferred to the charge receiving means and then to the inductive load.

As a sub-combination, the present invention also includes a conversion element comprising a housing; a first low voltage anode mounted to the housing, the first anode adapted to be connected to a voltage source; a second high voltage anode mounted to the housing, the second anode adapted to be connected to a voltage source; electrically conductive means positioned about the second anode and spaced therefrom for receiving a charge, the charge receiving means being mounted to the housing; and an output terminal communicating with the charge receiving means, said terminal adapted to be connected to an inductive load.

The invention also includes a method for providing power to an inductive load comprising the steps of providing a voltage source, pulsating a signal from said source; increasing the voltage of said signal; rectifying said signal; storing and increasing the signal; conducting said signal to a high voltage anode; providing a low voltage to a second anode to form a high energy discharge; electrostatically coupling the discharge to a charge receiving element; conducting the discharge to an inductive load; coupling a second capacitor to the load; and coupling the second capacitor to the source.

It is an aim of the present invention to provide a system for driving an inductive load which system is substantially more efficient than any now existing. Another object of the present invention is to provide a system for driving an inductive load which is reliable, is inexpensive and simply constructed.

The foregoing objects of the present invention together with various other objects, advantages, features and results thereof which will be evident to those skilled in the art in light of this disclosure may be achieved with the exemplary embodiment of the invention described in detail hereinafter and illustrated in the accompanying drawings.

DESCRIPTION OF THE PREFERRED EMBODIMENT

While the present invention is susceptible of various modifications and alternative constructions, an embodiment is shown in the drawings and will herein be described in detail. It should be understood however that it is not the intention to limit the invention to the particular form disclosed; but on the contrary, the invention is to cover all modifications, equivalents and alternative constructions falling within the spirit and scope of the invention as expressed in the appended claims.

There is disclosed herein an electrical driving system which, on theory, will convert low voltage electric energy from a source such as an electric storage battery to a high potential, high current energy pulse that is capable of developing a working force at the inductive output of the device that is more efficient than that which is capable of being developed directly from the energy source. The improvement in efficiency is further enhanced by the capability of the device to return that portion of the initial energy developed, and not used by the inductive load in the production of mechanical energy, to the same or second energy reservoir or source for use elsewhere, or for storage.

This system accomplishes the results stated above by harnessing the "electrostatic" or "impulse" energy created by a high-intensity spark generated within a specially constructed electrical conversion switching element tube. This element utilises a low-voltage anode, a high-voltage anode, and one or more "electrostatic" or charge receiving grids. These grids are of a physical size, and appropriately positioned, as to be compatible with the size of the tube, and therefore, directly related to the amount of energy to be anticipated when the device is operating.

The low-voltage anode may incorporate a resistive device to aid in controlling the amount of current drawn from the energy source. This low-voltage anode is connected to the energy source through a mechanical commutator or a solid-state pulser that controls the timing and duration of the energy spark within the element. The high-voltage anode is connected to a high-voltage potential developed by the associated circuits. An energy discharge occurs within the element when the external control circuits permit. This short duration, high-voltage, high-current energy pulse is captured by the "electrostatic" grids within the tube, stored momentarily, then transferred to the inductive output load.

The increase in efficiency anticipated in converting the electrical energy to mechanical energy within the inductive load is attributed to the utilisation of the most optimum timing in introducing the electrical energy to the load device, for the optimum period of time.

Further enhancement of energy conservation is accomplished by capturing a significant portion of the energy generated by the inductive load when the useful energy field is collapsing. This energy is normally dissipated in load losses that are contrary to the desired energy utilisation, and have heretofore been accepted because no suitable means had been developed to harness this energy and restore it to a suitable energy storage device.

The present invention is concerned with two concepts or characteristics. The first of these characteristics is observed with the introduction of an energising current through the inductor. The inductor creates a contrary force (counter-electromotive force or CEMP) that opposes the energy introduced into the inductor. This CEMP increases throughout the time the introduced energy is increasing.

In normal applications of an alternating-current to an inductive load for mechanical applications, the useful work of the inductor is accomplished prior to terminating the application of energy. The excess energy applied is thereby wasted.

Previous attempts to provide energy inputs to an inductor of time durations limited to that period when the optimum transfer of inductive energy to mechanical energy is occurring, have been limited by the ability of any such device to handle the high current required to optimise the energy transfer.

The second characteristic is observed when the energising current is removed from the inductor, As the current is decreased, the inductor generates an EMF that opposes the removal of current or, in other words, produces an energy source at the output of the inductor that simulates the original energy source, reduced by the actual energy removed from the circuit by the mechanical load. This "regenerated", or excess, energy has previously been lost due to a failure to provide a storage capability for this energy.

In this invention, a high-voltage, high-current, short duration energy pulse is applied to the inductive load by the conversion element. This element makes possible the use of certain of that energy impressed within an arc across a spark-gap, without the resultant deterioration of circuit elements normally associated with high energy electrical arcs.

This invention also provides for capture of a certain portion of the energy induced by the high inductive kick

produced by the abrupt withdrawal of the introduced current. This abrupt withdrawal of current is attendant upon the termination of the stimulating arc. The voltage spike so created is imposed upon a capacitor that couples the attendant current to a secondary energy storage device.

A novel, but not essential, circuit arrangement provides for switching the energy source and the energy storage device. This switching may be so arranged as to actuate automatically at predetermined times. The switching may be at specified periods determined by experimentation with a particular device, or may be actuated by some control device that measures the relative energy content of the two energy reservoirs.

Referring now to **Fig.1**, the system **10** will be described in additional detail. The potential for the high- voltage anode, **12** of the conversion element **14** is developed across the capacitor **16**. This voltage is produced by drawing a low current from a battery source **18** through the vibrator **20**. The effect of the vibrator is to create a pulsating input to the transformer **22**. The turns ratio of the transformer is chosen to optimise the volt- age applied to a bridge-type rectifier **24**. The output of the rectifier is then a series of high-voltage pulses of modest current. When the available source is already of the high voltage, AC type, it may be coupled directly to the bridge-type rectifier.

By repetitious application of these output pulses from the bridge-type rectifier to the capacitor **16**, a high-voltage, high-level charge is built up on the capacitor.

Control of the conversion switching element tube is maintained by a commutator **26**. A series of contacts mounted radially about a shafts or a solid-state switching device sensitive to time or other variable may be used for this control element. A switching element tube type one-way energy path **28** is introduced between the commutator device and the conversion switching element tube to prevent high energy arcing at the commutator current path. When the switching element tube is closed, current from the voltage source **18** is routed through a resistive element **30** and a low voltage anode **32**. This causes a high energy discharge between the anodes within the conversion switching element tube **14**.

The energy content of the high energy pulse is eletrostatically coupled to the conversion grids **34** of the conversion element. This electrostatic charge is applied through an output terminal **60** (**Fig.2**) across the load

inductance **36**, inducing a strong electromagnetic field about the inductive load. The intensity of this electromagnetic field is determined by the high electromotive potential developed upon the electrostatic grids and the very short time duration required to develop the energy pulse.

If the inductive load is coupled magnetically to a mechanical load, a strong initial torque is developed that may be efficiently utilised to produce physical work

Upon cessation of the energy pulse (arc) within the conversion switching element tube the inductive load is decoupled, allowing the electromagnetic field about the inductive load to collapse. The collapse of this energy field induces within the inductive load a counter EMF. This counter EMF creates a high positive potential across a second capacitor which, in turn, is induced into the second energy storage device or battery **40** as a charging current. The amount of charging current available to the battery **40** is dependent upon the initial conditions within the circuit at the time of discharge within the conversion switching element tube and the amount of mechanical energy consumed by the workload.

A spark-gap protection device **42** is included in the circuit to protect the inductive load and the rectifier elements from unduly large discharge currents. Should the potentials within the circuit exceed predetermined values, fixed by the mechanical size and spacing of the elements within the protective device, the excess energy is dissipated (bypassed) by the protective device to the circuit common (electrical ground).

Diodes **44** and **46** bypass the excess overshoot generated when the "Energy Conversion Switching Element Tube" is triggered. A switching element **U** allows either energy storage source to be used as the primary energy source, while the other battery is used as the energy retrieval unit. The switch facilitates interchanging the source and the retrieval unit at optimum intervals to be determined by the utilisation of the conversion switching element tube. This switching may be accomplished manually or automatically, as determined by the choice of switching element from among a large variety readily available for the purpose.

FIG. 3

FIG. 4

Fig.2, Fig.3, and Fig.4 show the mechanical structure of the conversion switching element tube **14**. An outer housing **50** may be of any insulative material such as glass. The anodes **12** and **22** and grids **34a** and **34b** are firmly secured by nonconductive spacer material **54**, and **56**. The resistive element **30** may be introduced into the low-voltage anode path to control the peak currents through the conversion switching element tube. The resistive element may be of a piece, or it may be built of one or more resistive elements to achieve the desired result.

The anode material may be identical for each anode, or may be of differing materials for each anode, as dictated by the most efficient utilisation of the device, as determined by appropriate research at the time of production for the intended use. The shape and spacing of the electrostatic grids is also susceptible to variation with application (voltage, current, and energy requirements).

It is the contention of the inventor that by judicious mating of the elements of the conversion switching element tube, and the proper selection of the components of the circuit elements of the system, the desired theoretical results may be achieved. It is the inventor's contention that this mating and selection process is well within the capabilities of intensive research and development technique.

Let it be stated here that substituting a source of electric alternating-current subject to the required current and/or voltage shaping and/or timing, either prior to being considered a primary energy source, or thereafter, should not be construed to change the described utilisation or application of primary energy in any way. Such energy conversion is readily achieved by any of a multitude of well established principles. The preferred embodiment of this invention merely assumes optimum utilisation and optimum benefit from this invention when used with portable energy devices similar in principle to the wet-cell or dry-cell battery.

This invention proposes to utilise the energy contained in an internally generated high-voltage electric spike (energy pulse) to electrically energise an inductive load.: this inductive load being then capable of converting the energy so supplied into a useful electrical or mechanical output.

In operation the high-voltage, short-duration electric spike is generated by discharging the capacitor **16** across the spark-gap in the conversion switching element tube. The necessary high-voltage potential is stored on the capacitor in incremental, additive steps from the bridge-type rectifier **24**. When the energy source is a direct-current electric energy storage device, such as the battery **12**, the input to the bridge rectifier is provided by the voltage step-up transformer **22**, that is in turn energised from the vibrator **20**, or solid-state chopper, or similar device to properly drive the transformer and rectifier circuits.

When the energy source is an alternating-current, switches **64** disconnect transformer **22** and the input to the bridge-type rectifier **24** is provided by the voltage step-up transformer **66**, that is in turn energised from the vibrator **20**, or solid-state chopper, or similar device to properly drive the transformer and rectifier circuits.

The repetitions output of the bridge rectifier incrementally increases the capacitor charge toward its maximum. This charge is electrically connected directly to the high-voltage anode **12** of the conversion switching element tube. When the low-voltage anode **32** is connected to a source of current, an arc is created in the spark-gap designated **62** of the conversion switching element tube equivalent to the potential stored on the high-voltage anode, and the current available from the low-voltage anode.

Because the duration of the arc is very short, the instantaneous voltage, and instantaneous current may both be very high. The instantaneous peak apparent power is therefore, also very high. Within the conversion switching element tube, this energy is absorbed by the grids **34a** and **34b** mounted circumferentially about the interior of the tube.

Control of the energy spike within the conversion switching element tube is accomplished by a mechanical, or

solid-state commutator, that closes the circuit path from the low-voltage anode to the current source at that moment when the delivery of energy to the output load is most auspicious. Any number of standard high-accuracy, variable setting devices are available for this purpose. When control of the repetitive rate of the system's output is required, it is accomplished by controlling the time of connection at the low-voltage anode.

Thus there can be provided an electrical driving system having a low-voltage source coupled to a vibrator, a transformer and a bridge-type rectifier to provide a high voltage pulsating signal to a first capacitor. Where a high-voltage source is otherwise available, it may be coupled direct to a bridge-type rectifier, causing a pulsating signal to a first capacitor. The capacitor in turn is coupled to a high-voltage anode of an electrical conversion switching element tube. The element also includes a low-voltage anode which in turn is connected to a voltage source by a commutator, a switching element tube, and a variable resistor. Mounted around the high-voltage anode is a charge receiving plate which in turn is coupled to an inductive load to transmit a high-voltage discharge from the element to the load. Also coupled to the load is a second capacitor for storing the back EMF created by the collapsing electrical field of the load when the current to the load is blocked. The second capacitor in turn is coupled to the voltage source.

ELECTRICAL MOTOR / GENERATOR

This version of the patent has been re-worded in an attempt to make it easier to read and understand. It describes the design of a pulsed electromagnet / permanent magnet motor which is capable of a higher power output than it's own power input.

ABSTRACT

An electrodynamic motor-generator has a salient pole permanent magnet rotor interacting with salient stator poles to form a machine operating on the magnetic reluctance principle. The intrinsic ferromagnetic power of the magnets provides the drive torque by bringing the poles into register whilst current pulses demagnetise the stator poles as the poles separate. In as much as less power is needed for stator demagnetisation than is fed into the reluctance drive by the thermodynamic system powering the ferromagnetic state, the machine operates regeneratively by virtue of stator winding interconnection with unequal number of rotor and stator poles. A rotor construction is disclosed (**Fig.6** and **Fig.7**). The current pulse may be such as to cause repulsion of the rotor poles.

FIELD OF THE INVENTION

This invention relates to a form of electric motor which serves a generating function in that the machine can act regeneratively to develop output electrical power or can generate mechanical drive torque with unusually high efficiency in relation to electrical power input.

The field of invention is that of switched reluctance motors, meaning machines which have salient poles and operate by virtue of the mutual magnetic attraction and/or repulsion as between magnetised poles.

The invention particularly concerns a form of reluctance motor which incorporates permanent magnets to establish magnetic polarisation.

BACKGROUND OF THE INVENTION

There have been proposals in the past for machines in which the relative motion of magnets can in some way develop unusually strong force actions which are said to result in more power output than is supplied as electrical input.

By orthodox electrical engineering principles such suggestions have seemed to contradict accepted principles of physics, but it is becoming increasingly evident that conformity with the first law of thermodynamics allows a gain in the electromechanical power balance provided it is matched by a thermal cooling.

In this sense, one needs to extend the physical background of the cooling medium to include, not just the machine structure and the immediate ambient environment, but also the sub-quantum level of what is termed, in modern physics, the zero-point field. This is the field activity of the vacuum medium which exists in the space between atomic nuclei and atomic electrons and is the seat of the action which is that associated with the Planck constant. Energy is constantly being exchanged as between that activity and coextensive matter forms but normally these energy fluctuations preserve, on balance, an equilibrium condition so that this action passes unnoticed at the technology level.

Physicists are becoming more and more aware of the fact that, as with gravitation, so magnetism is a route by which we can gain access to the sea of energy that pervades the vacuum. Historically, the energy balance has been written in mathematical terms by assigning 'negative' potential to gravitation or magnetism. However, this is only a disguised way of saying that the vacuum field, suitably influenced by the gravitating mass of a body in the locality or by magnetism in a ferromagnet has both the capacity and an urge to shed energy.

Now, however, there is growing awareness of the technological energy generating potential of this field background and interest is developing in techniques for 'pumping' the coupling between matter and vacuum field to derive power from that hidden energy source. Such research may establish that this action will draw on the

2.7K cosmic background temperature of the space medium through which the Earth travels at some 400 km/s. The effect contemplated could well leave a cool 'vapour trail' in space as a machine delivering heat, or delivering a more useful electrical form of energy that will revert to heat, travels with body Earth through that space.

In pure physics terms, relevant background is of recent record in the August 1993 issue of Physical Review E, vol. 48, pp. 1562-1565 under the title: 'Extracting energy and heat from the vacuum', authored by D. C. Cole and H. E. Puthoff. Though the connection is not referenced in that paper, one of its author's presented experimental evidence on that theme at an April 1993 conference held in Denver USA. The plasma power generating device discussed at that conference was the subject of U. S. Patent No. 5,018,180, the inventor of record being K. R. Shoulders.

The invention, to be described below, operates by extracting energy from a magnetic system in a motor and the relevant scientific background to this technology can be appreciated from the teachings of E. B. Moullin, a Cambridge Professor of Electrical Engineering who was a President of the Institution of Electrical Engineers in U. K. That prior art will be described below as part of the explanation of the operation of the invention.

The invention presented here concerns specific structural design features of a machine adapted for robust operation, but these also have novelty and special merit in a functional operation. What is described is quite distinct from prior art proposals, one being a novel kind of motor proposed by Gareth Jones at a 1988 symposium held in Hull, Canada under the auspices of the Planetary Association for Clean Energy. Jones suggested the adaptation of an automobile alternator which generates three-phase AC for rectification and use as a power supply for the electrics in the automobile. This alternator has a permanent magnet rotor and Jones suggested that it could be used, with high efficiency gain and torque performance, by operating it as a motor with the three-phase winding circuit excited so as to promote strong repulsion between the magnet poles and the stator poles after the poles had come into register.

However, the Jones machine is not one exploiting the advantages of the invention to be described, because it is not strictly a reluctance motor having salient poles on both stator and rotor. The stator poles in the Jones machine are formed by the winding configuration in a slotted stator form, the many slots being uniformly distributed around the inner circumference of the stator and not constituting a pole system which lends itself to the magnetic flux actions to be described by reference to the E. B. Moullin experiment.

The Jones machine operates by generating a rotating stator field which, in a sense, pushes the rotor poles forward rather than pulling them in the manner seen in the normal synchronous motor. Accordingly, the Jones machine relies on the electric current excitation of the motor producing a field system which rotates smoothly but has a polarity pattern which is forced by the commutation control to keep behind the rotor poles in asserting a continuous repulsive drive.

Another prior art proposal which is distinguished from this invention is that of one of the applicants, H. Aspden, namely the subject of U.K. Patent No. 2,234,863 (counterpart U.S. Patent Serial No.4,975,608). Although this latter invention is concerned with extracting energy from the field by the same physical process as the subject invention, the technique for accessing that energy is not optimum in respect of the structure or method used. Whereas in this earlier disclosure, the switching of the reluctance drive excited the poles in their approach phase, the subject invention, in one of its aspects, offers distinct advantages by demagnetisation or reversal of magnetisation in the pole separation phase of operation.

There are unexpected advantages in the implementation proposed by the subject invention, inasmuch as recent research has confirmed that it requires less input power to switch off the mutual attraction across an air gap between a magnet and an electromagnet than it does to switch it on. Usually, in electromagnetism, a reversal symmetry is expected, arising from conventional teaching of the way forward and back magnetomotive forces govern the resulting flux in a magnetic circuit.

This will be further explained after describing the scope of the invention.

BRIEF DESCRIPTION OF THE INVENTION

According to one aspect of the invention, an electrodynamic motor/generator machine comprises a stator configured to provide a set of stator poles, a corresponding set of magnetising windings mounted on the stator pole set, a rotor having two sections each of which has a set of salient pole pieces, the rotor sections being axially spaced along the axis of rotation of the rotor, rotor magnetisation means disposed between the two rotor sections arranged to produce a unidirectional magnetic field which magnetically polarises the rotor poles, whereby the pole faces of one rotor section all have a north polarity and the pole faces of the other rotor section all have a south polarity and electric circuit connections between an electric current source and the stator magnetising windings arranged to regulate the operation of the machine by admitting current pulses for a duration determined according

to the angular position of the rotor, which pulses have a direction tending to oppose the polarisation induced in the stator by the rotor polarisation as stator and rotor poles separate from an in-register position, whereby the action of the rotor magnetisation means provides a reluctance motor drive force to bring stator and rotor poles into register and the action of the stator magnetisation windings opposes the counterpart reluctance braking effect as the poles separate.

According to a feature of the invention, the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide demagnetisation of the stator poles as the stator and rotor poles separate from an in-register position.

In this regard it is noted that in order to suppress the reluctance drive torque or brake torque, depending upon whether poles are converging or separating, a certain amount of electrical power must be fed to the magnetising windings on the stator. In a sense these windings are really 'demagnetising windings' because the polarity of the circuit connections admit the pulse current in the demagnetising direction.

However, it is more usual to refer to windings on magnetic cores as 'magnetising windings' even though they can function as primary windings or secondary windings, the former serving the magnetisation function with input power and the latter serving a demagnetising function with return of power.

According to another feature of the invention, the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide a reversal of magnetic flux direction in the stator poles as the stator and rotor poles separate from an in-register position, whereby to draw on power supplied from the electric current source to provide additional forward drive torque.

According to a further feature of the invention, the electric current source connected to a stator magnetising winding of a first stator pole comprises, at least partially, the electrical pulses induced in the stator magnetising winding of a different second stator pole, the stator pole set configuration in relation to the rotor pole set configuration being such that the first stator pole is coming into register with a rotor pole as the second stator pole separates from its in-register position with a rotor pole.

This means that the magnetising windings of two stator poles are connected so that both serve a 'demagnetising' function, one in resisting the magnetic action of the mutual attraction in pulling poles into register, an action which develops a current pulse output and one in absorbing this current pulse, again by resisting the magnetic inter-pole action to demagnetise the stator pole as its associated rotor pole separates.

In order to facilitate the function governed by this circuit connection between stator magnetising windings, a phase difference is needed and this is introduced by designing the machine to have a different number of poles in a set of stator poles from the number of rotor poles in each rotor section. Together with the dual rotor section feature, this has the additional merit of assuring a smoother torque action and reducing magnetic flux fluctuations and leakage effects which contribute substantially to machine efficiency.

Thus, according to another feature of the invention, the stator configuration provides pole pieces which are common to both rotor sections in the sense that when stator and rotor poles are in-register the stator pole pieces constitute bridging members for magnetic flux closure in a magnetic circuit including that of the rotor magnetisation means disposed between the two rotor sections.

Preferably, the number of poles in a set of stator poles and the number of rotor poles in each section do not share a common integer factor, the number of rotor poles in one rotor section is the same as that in the other rotor section and the number of poles in a stator set and the number of poles in a rotor section differs by one, with the pole faces being of sufficient angular width to assure that the magnetic flux produced by the rotor magnetisation means can find a circular magnetic flux closure route through the bridging path of a stator pole and through corresponding rotor poles for any angular position of the rotor.

It is also preferable from a design viewpoint for the stator pole faces of this invention to have an angular width that is no greater than half the angular width of a rotor pole and for the rotor sections to comprise circular steel laminations in which the rotor poles are formed as large teeth at the perimeter with the rotor magnetisation means comprising a magnetic core structure the end faces of which abut two assemblies of such laminations forming the two rotor sections.

According to a further feature of the invention, the rotor magnetisation means comprises at least one permanent magnet located with its polarisation axis parallel with the rotor axis. The motor-generator may include an apertured metal disc that is of a non-magnetisable substance mounted on a rotor shaft and positioned intermediate the two rotor sections, each aperture providing location for a permanent magnet, whereby the centrifugal forces acting on the permanent magnet as the rotor rotates are absorbed by the stresses set up in the

disc. Also, the rotor may be mounted on a shaft that is of a non-magnetisable substance, whereby to minimise magnetic leakage from the rotor magnetising means through that shaft.

According to another aspect of the invention, an electrodynamic motor-generator machine comprises a stator configured to provide a set of stator poles, a corresponding set of magnetising windings mounted on the stator pole set, a rotor having two sections each of which has a set of salient pole pieces, the rotor sections being axially spaced along the axis of rotation of the rotor, rotor magnetisation means incorporated in the rotor structure and arranged to polarise the rotor poles, whereby the pole faces of one rotor section all have a north polarity and the pole faces of the other rotor section all have a south polarity and electric circuit connections between an electric current source and the stator magnetising windings arranged to regulate the operation of the machine by admitting current pulses for a duration determined according to the angular position of the rotor, which pulses have a direction tending to oppose the polarisation induced in the stator by the rotor polarisation as stator and rotor poles separate from an in-register position, whereby the action of the rotor magnetisation means provides a reluctance motor drive force to bring stator and rotor poles into register and the action of the stator magnetisation windings opposes the counterpart reluctance braking effect as the poles separate.

According to a feature of this latter aspect of the invention, the electric current source connected to a stator magnetising winding of a first stator pole comprises, at least partially, the electrical pulses induced in the stator magnetising winding of a different second stator pole, the stator pole set configuration in relation to the rotor pole set configuration being such that the first stator pole is coming into register with a rotor pole as the second stator pole separates from its in-register position with a rotor pole.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG.1

Fig.1 presents magnetic core test data showing how the volt-amp reactance power required to set up a constant magnetic flux action in an air gap, as assured by constant AC voltage excitation of a magnetising winding, falls short of the associated power of the potential implicit in the force action across that air gap.

FIG.2

Fig.2 depicts the test structure to which Fig. 1 data applies.

FIG.3

Fig.3 depicts the magnetisation action at work in causing magnetic flux to traverse an air-gap and turn a corner in a circuit through a magnetic core.

FIG. 4

Fig.4 shows the configuration of a test device used to prove the operating principles of the invention described.

FIG.5

Fig.5 in its several illustrations depicts the progressive rotor pole to stator pole relationship as a rotor turns through a range of angular positions in a preferred embodiment of a machine according to the invention.

FIG. 6

Fig.6 shows the form of a disc member which provides location for four permanent magnets in the machine described.

FIG.7

Fig.7 shows a cross-section of the magnetic circuit structure of a machine embodying the invention.

FIG.8

Fig.8 shows a six stator pole configuration with a seven pole rotor and depicts a schematic series connected linking of the magnetising windings of diametrically opposite stator poles.

DETAILED DESCRIPTION OF THE INVENTION

The fact that one can extract energy from the source which powers the intrinsic ferromagnetic state is not explicitly evident from existing textbooks, but it is implicit and, indeed, does become explicit once pointed out, in one textbook authored by E. B. Moullin. His book 'The Principles of Electromagnetism' published by Clarendon Press, Oxford (3rd Edition, 1955) describes on pages 168-174 an experiment concerned with the effect of air gaps between poles in a magnetic circuit. The data obtained are reproduced in **Fig.1**, where Professor Moullin shows a curve representing AC current input for different air gaps, given that the voltage supplied is constant. In the same figure, Moullin presents the theoretical current that would need to be applied to sustain the same voltage, and so the related pole forces across the air gap, assuming (a) no flux leakage and (b) that there is complete equality between inductive energy input and the mechanical energy potential for the magnetisation that is established in the air gap in a quarter-cycle period at the AC power excitation frequency.

FIG.1

The data show that, even though the level of magnetic polarisation is well below the saturation value, being confined to a range that is regarded as the linear permeability range in transformer design, there is a clear drop-off of current, and so the volt-amp reactive power input needed, as current increases, compared with that predicted by the mechanical potential built up in the air gaps. Unless leakage flux is excessive, here was clear evidence of anomalous energy activity.

Moullin discusses the leakage flux inferred by this experiment but points out that there is considerable mystery in why the effect of a small gap, which should certainly not result in much flux leakage in the gap region, nevertheless has an enormous effect in causing what has to be substantial leakage in the light of the energy discrepancy. Moullin did not contemplate that energy had been fed in from the zero-point field system and so he left the issue with the statement that it was virtually impossible to predict leakage flux by calculation.

He was, of course, aware of magnetic domain structure and his argument was that the leakage flux problem was connected with what he termed a 'yawing' action of the flux as it passes around the magnetic circuit. Normally, provided the level of polarisation is below the knee of the B-H curve, which occurs at about 70% of saturation in iron cores of general crystal composition, it requires very little magnetising field to change the magnetic flux density. This is assuming that every effort is made to avoid air gaps. The action involves domain wall movements so that the magnetic states of adjacent domains switch to different crystal axes of easy magnetisation and this involves very little energy change.

However, if there is an air gap ahead in the flux circuit and the magnetising winding is not sitting on that air gap, the iron core itself has to be the seat of a progressive field source linking the winding and the gap. It can only serve in that sense by virtue of the lines of flux in the domains being forced to rotate somewhat from the preferred easy axes of magnetisation, with the help of the boundary surfaces around the whole core. This action means that, forcibly, and consequential upon the existence of the air gap, the flux must be carried through the core by

that 'yawing' action. It means that substantial energy is needed to force the establishment of those fields within the iron core. More important, however, from the point of view of this invention, it means that the intrinsic magnetic polarisation effects in adjacent magnetic domains in the iron cease to be mutually parallel or orthogonal so as to stay directed along axes of easy magnetisation. Then, in effect, the magnetising action is not just that of the magnetising winding wrapped around the core but becomes also that of adjacent ferromagnetic polarisation as the latter act in concert as vacuum-energy powered solenoids and are deflected into one another to develop the additional forward magnetomotive forces.

The consequences of this are that the intrinsic ferromagnetic power source with its thermodynamic ordering action contributes to doing work in building up forces across the air gap. The task, in technological terms, is then to harness that energy as the gap is closed, as by poles coming together in a reluctance motor, and avoid returning that energy as the poles separate, this being possible if the controlling source of primary magnetisation is well removed from the pole gap and the demagnetisation occurs when the poles are at the closest position.

This energy situation is evident in the Moullin data, because the constant AC voltage implies a constant flux amplitude across the air gap if there is no flux leakage in the gap region. A constant flux amplitude implies a constant force between the poles and so the gap width in relation to this force is a measure of the mechanical energy potential of the air gap. The reactive volt-amp power assessment over the quarter-cycle period representing the polarisation demand can then be compared with the mechanical energy so made available. As already stated, this is how Moullin deduced the theoretical current curve. In fact, as his data show, he needed less current than the mechanical energy suggested and so he had in his experiment evidence of the vacuum energy source that passed unnoticed and is only now revealing itself in machines that can serve our energy needs.

In the research leading to this patent application the Moullin experiment has been repeated to verify a condition where a single magnetising winding serves three air gaps. The Moullin test configuration is shown in **Fig.2**, but in repeating the experiment in the research leading to this invention, a search coil was mounted on the bridging member and this was used to compare the ratio of the voltage applied to the magnetising winding and that induced in the search coil.

The same fall-off feature in current demand was observed, and there was clear evidence of substantial excess energy in the air gap. This was in addition to the inductive energy that necessarily had to be locked into the magnetic core to sustain the 'yawing' action of the magnetic flux already mentioned.

It is therefore emphasised that, in priming the flux 'yawing' action, energy is stored inductively in the magnetic core, even though this has been deemed to be the energy of flux leakage outside the core. The air gap energy is also induction energy. Both energies are returned to the source winding when the system is demagnetised, given a fixed air gap.

If, however, the air gap closes after or during magnetisation, much of that inductive energy goes into the mechanical work output. Note then that the energy released as mechanical work is not just that stored in the air gap but is that stored in sustaining the 'yaw'. Here, then is reason to expect an even stronger contribution to the dynamic machine performance, one that was not embraced by the calculation of the steady-state situation.

Given the above explanation of the energy source, the structural features which are the subject of this invention will now be described.

The 'yawing' action is depicted in **Fig.3**, which depicts how magnetic flux navigates a right-angled bend in a magnetic core upon passage through an air gap. By over-simplification it is assumed that the core has a crystal structure that has a preferred axis of magnetisation along the broken line path. With no air gap, the current needed by a magnetising winding has only to provide enough magnetomotive force to overcome the effects of non-magnetic inclusions and impurities in the core substance and very high magnetic permeabilities can apply. However, as soon as the air gap develops, this core substance has to find a way of setting up magnetomotive force in regions extending away from the locality of the magnetising winding. It cannot do this unless its effect is so powerful that the magnetic flux throughout the magnetic circuit through the core substance is everywhere deflected from alignment with a preferred easy axis of magnetisation. Hence the flux vectors depicted by the arrows move out of alignment with the broken line shown.

There is a 'knock-on' effect progressing all the way around the core from the seat of the magnetising winding and, as already stated, this harnesses the intrinsic ferromagnetic power that, in a system with no air gap, could only be affected by magnetisation above the knee of the B-H curve. Magnetic flux rotation occurs above that knee, whereas in an ideal core the magnetism develops with very high permeability over a range up to that knee, because it needs very little power to displace a magnetic domain wall sideways and promote a 900 or a1800 flux reversal. Indeed, one can have a magnetic permeability of 10,000 below the knee and 100 above the knee, the latter reducing progressively until the substance saturates magnetically.

In the situation depicted in **Fig.2** and **Fig.3** the field strength developed by the magnetising windings 1 on magnetic core 2 has to be higher, the greater the air gap, in order to achieve the same amount of magnetisation as measured by the voltage induced in a winding (not shown) on the bridging member 3. However, by virtue of that air gap there is potential for harnessing energy supplied to that air gap by the intrinsic zero-point field that accounts for the magnetic permeability being over unity and here one can contemplate very substantial excess energy potential, given incorporation in a machine design which departs from convention.

One of the applicants has built an operative test machine which is configured as depicted schematically in **Fig.4**. The machine has been proved to deliver substantially more mechanical power output than is supplied as electrical input, as much as a ratio of 7:1 in one version, and it can act regeneratively to produce electrical power.

FIG. 4

What is shown in **Fig.4** is a simple model designed to demonstrate the principle of operation. It comprises a rotor in which four permanent magnets 4 are arrayed to form four poles. The magnets are bonded into four sectors of a non-magnetic disc 5 using a high density polyurethane foam filler and the composite disc is then assembled on a brass spindle 6 between a split flange coupling. Not shown in the figure is the structure holding the spindle vertically in bearings or the star wheel commutator assembly attached to the upper shaft of the spindle.

Note that the magnets present north poles at the perimeter of the rotor disc and that the south poles are held together by being firmly set in the bonding material. A series of four stator poles were formed using magnetic cores from standard electromagnetic relays were positioned around the rotor disc as shown. The magnetising windings 7 on these cores are shown to be connected in series and powered through commutator contacts 8 by a DC power supply. Two further stator cores formed by similar electromagnetic relay components are depicted by their windings 9 in the intermediate angle positions shown and these are connected in series and connected to a rectifier 10 bridged by a capacitor 11.

The rotor spindle **6** is coupled with a mechanical drive (not shown) which harnesses the torque developed by the motor thus formed and serves as a means for measuring output mechanical power delivered by the machine.

In operation, assuming that the rotor poles are held initially off-register with the corresponding stator poles and the hold is then released, the strong magnetic field action of the permanent magnets will turn the rotor to bring the stator and rotor poles into register. A permanent magnet has a strong attraction for soft iron and so this initial impulse of rotation is powered by the potential energy of the magnets.

Now, with the rotor acting as a flywheel and having inertia it will have a tendency to over-shoot the in-register pole position and that will involve a reverse attraction with the result that the rotor will oscillate until damping action brings it to rest. However, if the contacts of the commutating switch are closed as the poles come

The commutating switch **8** needs only to be closed for a limited period of angular travel following the top dead centre in-register position of the stator and rotor poles. The power supplied through that switch by those pulses will cause the rotor to continue rotating and high speeds will be achieved as the machine develops its full motor function.

Tests on such a machine have shown that more mechanical power can be delivered than is supplied electrically by the source powering the action through the commutating switch. The reason for this is that, whereas the energy in the air gap between rotor and stator poles which is tapped mechanically as the poles come into register is provided by the intrinsic power of the ferromagnet, a demagnetising winding on the part of the core system coupled across that air gap needs very little power to eliminate the mechanical force acting across that air gap. Imagine such a winding on the bridging member shown in **Fig.2**. The action of current in that winding, which sits astride the 'yawing' flux in that bridging member well removed from the source action of the magnetising windings **1**, is placed to be extremely effective in resisting the magnetising influence communicated from a distance. Hence very little power is needed to overcome the magnetic coupling transmitted across the air gap.

Although the mutual inductance between two spaced-apart magnetising windings has a reciprocal action, regardless of which winding is primary and which is secondary, the action in the particular machine situation being described involves the 'solenoidal' contribution represented by the 'yawing' ferromagnetic flux action. The latter is not reciprocal inasmuch as the flux 'yaw' depends on the geometry of the system. A magnetising winding directing flux directly across an air gap has a different influence on the action in the ferromagnetic core from one directing flux lateral to the air gap and there is no reciprocity in this action.

In any event, the facts of experiment do reveal that, owing to a significant discrepancy in such mutual interaction, more mechanical power is fed into the rotor than is supplied as input from the electrical source.

This has been further demonstrated by using the two stator windings **9** to respond in a generator sense to the passage of the rotor poles. An electrical pulse is induced in each winding by the passage of a rotor pole and this is powered by the inertia of the rotor disc **5**. By connecting the power so generated, to charge the capacitor **11**, the DC power supply can be augmented to enhance the efficiency even further.

Indeed, the machine is able to demonstrate the excess power delivery from the ferromagnetic system by virtue of electrical power generation charging a battery at a greater rate than a supply battery is discharged.

This invention is concerned with a practical embodiment of the motor-generator principles just described and aims, in its preferred aspect, to provide a robust and reliable machine in which the tooth stresses in the rotor poles, which are fluctuating stresses communicating high reluctance drive torque, are not absorbed by a ceramic permanent magnet liable to rupture owing to its brittle composition.

Another object is to provide a structure which can be dismantled and reassembled easily to replace the permanent magnets, but an even more important object is that of minimising the stray leakage flux oscillations from the powerful permanent magnets. Their rotation in the device depicted in **Fig.4** would cause excessive eddy-current induction in nearby metal, including that of the machine itself, and such effects are minimised if the flux changes are confined to paths through steel laminations and if the source flux from the magnets has a symmetry or near symmetry about the axis of rotation.

Thus, the ideal design with this in mind is one where the permanent magnet is a hollow cylinder located on a non-magnetic rotor shaft, but, though that structure is within the scope of this invention, the machine described will utilise several separate permanent magnets approximating, in function, such a cylindrical configuration.

Referring to **Fig.4**, it will further be noted that the magnetic flux emerging from the north poles will have to find its way along leakage paths through air to re-enter the south poles. For periods in each cycle of machine operation

the flux will be attracted through the stator cores, but the passage through air is essential and so the power of the magnets is not used to full advantage and there are those unwanted eddy-current effects.

To overcome this problem the invention provides for two separate rotor sections and the stator poles become bridging members, which with optimum design, allow the flux from the magnets to find a route around a magnetic circuit with minimal leakage through air as the flux is directed through one or other pairs of air gaps where the torque action is developed.

FIG. 5

Reference is now made to **Fig. 5** and the sequence of rotor positions shown. Note that the stator pole width can be significantly smaller than that of the rotor poles. Indeed, for operation using the principles of this invention, it is advantageous for the stator to have a much smaller pole width so as to concentrate the effective pole region. A stator pole width of half that of the rotor is appropriate but it may be even smaller and this has the secondary advantage of requiring smaller magnetising windings and so saving on the loss associated with the current circuit.

FIG. 7

The stator has eight pole pieces formed as bridging members **12**, more clearly represented in **Fig. 7**, which shows a sectional side view through two rotor sections **13** axially spaced on a rotor shaft **14**. There are four permanent magnets **15** positioned between these rotor sections and located in apertures **16** in a disc **17** of a non-magnetic

substance of high tensile strength, the latter being shown in **Fig.6**. The rotor sections are formed from disc laminations of electrical steel which has seven large teeth, the salient poles. Magnetising windings **18** mounted on the bridging members **12** constitute the system governing the action of the motor-generator being described.

The control circuitry is not described as design of such circuitry involves ordinary skill possessed by those involved in the electrical engineering art.

It suffices, therefore, to describe the merits of the structural design configuration of the core elements of the machine. These concern principally the magnetic action and, as can be imagined from **Fig.7**, the magnetic flux from the magnets enters the rotor laminations by traversing the planar faces of the laminations and being deflected into the plane of the laminations to pass through one or other of the stator pole bridging members, returning by a similar route through the other rotor.

By using eight stator poles and seven rotor poles, the latter having a pole width equal to half the pole pitch in an angular sense, it will be seen from **Fig.5**, that there is always a flux passage across the small air gap between stator and rotor poles. However, as one pole combination is in-register the diametrically-opposed pole combinations are out-of register.

As described by reference to **Fig.4** the operation of the machine involves allowing the magnet to pull stator and rotor poles into register and then, as they separate, pulsing the winding on the relevant stator member to demagnetise that member. In the **Fig.4** system, all the stator magnetising windings were pulsed together, which is not an optimum way in which to drive a multi-pole machine.

In the machine having the pole structure with one less rotor pole than stator poles (or an equivalent design in which there is one less stator pole than rotor poles) this pulsing action can be distributed in its demand on the power supply, and though this makes the commutation switch circuit more expensive the resulting benefit outweighs that cost. However, there is a feature of this invention by which that problem can be alleviated if not eliminated.

Suppose that the rotor has the position shown in **Fig.5(a)** with the rotor pole denoted **R1** midway between stator poles **S1** and **S2** and imagine that this is attracted towards the in-register position with stator pole **S2**. Upon reaching that in-register position, as shown in **Fig.5(c)**, suppose that the magnetising winding of stator pole **S2** is excited by a current pulse which is sustained until the rotor reaches the **Fig.5(e)** position.

The combination of these two actions will have imparted a forward drive impulse powered by the permanent magnet in the rotor structure and the current pulse which suppresses braking action will have drawn a smaller amount of energy from the electrical power source which supplies it. This is the same process as was described by reference to **Fig.4**.

However, now consider the events occurring in the rotor action diametrically opposite that just described. In the **Fig.5(a)** position rotor pole **R4** has come fully into register with stator pole **S5** and so stator pole **S5** is ready to be demagnetised. However, the magnetic coupling between the rotor and stator poles is then at its strongest. Note, however, that in that **Fig.5(a)** position **R5** is beginning its separation from stator poles and the magnetising winding of stator pole **S6** must then begin draw power to initiate demagnetisation. During that following period of pole separation the power from the magnet is pulling **R1** and **S2** together with much more action than is needed to generate that current pulse needed to demagnetise **S6**. It follows, therefore, that, based on the research findings of the regenerative excitation in the test system of **Fig.4**, the series connection of the magnetising windings on stators **S2** and **S6** will, without needing any commutative switching, provide the regenerative power needed for machine operation.

The complementary action of the two magnetising windings during the pole closure and pole separation allows the construction of a machine which, given that the zero-point vacuum energy powering the ferromagnet is feeding input power, will run on that source of energy and thereby cool the sustaining field system.

There are various design options in implementing what has just been proposed. Much depends upon the intended use of the machine. If it is intended to deliver mechanical power output the regenerative electrical power action can all be used to power the demagnetisation with any surplus contributing to a stronger drive torque by reversing the polarity of the stator poles during pole separation.

If the object is to generate electricity by operating in generator mode then one could design a machine having additional windings on the stator for delivering electrical power output. However, it seems preferable to regard the machine as a motor and maximise its efficiency in that capacity whilst using a mechanical coupling to an alternator of conventional design for the electrical power generation function.

In the latter case it would still seem preferable to use the self-excitation feature already described to reduce commutation switching problems.

The question of providing for machine start-up can be addressed by using a separate starter motor powered from an external supply or by providing for current pulsing limited to, say, two stator poles. Thus, for example, with the eight stator pole configuration, the cross-connected magnetising windings could be limited to three stator pairs, with two stator magnetising windings left free for connection to a pulsed external supply source.

FIG. 8

If the latter feature were not required, then the stator magnetising windings would all be connected in pairs on a truly diametrically opposite basis. Thus **Fig. 8** shows a rotor-stator configuration having six stator poles interacting with seven rotor poles and stator magnetising windings linked together in pairs.

The invention, therefore, offers a wide range of implementation possibilities, which, in the light of this disclosure will become obvious to persons skilled in the electrical engineering art, all based, however, on the essential but simple principle that a rotor has a set of poles of common polarity which are attracted into register with a set of stator poles that are suppressed or reversed in polarity magnetically during pole separation. The invention, however, also offers the important feature of minimising commutation and providing further for a magnetic flux closure that minimises the leakage flux and fluctuations of leakage flux and so contributes to efficiency and high torque performance as well as durability and reliability of a machine incorporating the invention.

It is noted that although a machine has been described which uses two rotor sections it is possible to build a composite version of the machine having several rotor sections. In the eventuality that the invention finds use in very large motor-generator machines the problem of providing very large magnets can be overcome by a design in which numerous small magnets are assembled. The structural concept described by reference to **Fig. 6** in providing locating apertures to house the magnets makes this proposal highly feasible. Furthermore, it is possible to replace the magnets by a steel cylinder and provide a solenoid as part of the stator structure and located between the rotor sections. This would set up an axial magnetic field magnetising the steel cylinder and so polarising the rotor. However, the power supplied to that solenoid would detract from the power generated and so such a machine would not be as effective as the use of permanent magnets such as are now available.

Nevertheless, should one see significant progress in the development of warm superconductor materials, it may become feasible to harness the self-generating motor-generator features of the invention, with its self-cooling properties, by operating the device in an enclosure at low temperatures and replacing the magnets by a superconductive stator supported solenoid.

CLAIMS

1. An electrodynamic motor-generator machine comprising a stator configured to provide a set of stator poles, a corresponding set of magnetising windings mounted on the stator pole set, a rotor having two sections each of which has a set of salient pole pieces, the rotor sections being axially spaced along the axis of rotation of the rotor, rotor magnetisation means disposed between the two rotor sections arranged to produce a unidirectional magnetic field which magnetically polarises the rotor poles, whereby the pole faces of one rotor section all have a north polarity and the pole faces of the other rotor section all have a south polarity and electric circuit connections between an electric current source and the stator magnetising windings arranged to regulate the operation of the machine by admitting current pulses for a duration determined according to the angular position of the rotor, which pulses have a direction tending to oppose the polarisation induced in the stator by

the rotor polarisation as stator and rotor poles separate from an in-register position, whereby the action of the rotor magnetisation means provides a reluctance motor drive force to bring stator and rotor poles into register and the action of the stator magnetisation windings opposes the counterpart reluctance braking effect as the poles separate.

2. A motor-generator according to claim 1, wherein the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide demagnetisation of the stator poles as the stator and rotor poles separate from an in-register position.
3. A motor-generator according to claim 1, wherein the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide a reversal of magnetic flux direction in the stator poles as the stator and rotor poles separate from an in-register position, whereby to draw on power supplied from the electric current source to provide additional forward drive torque.
4. A motor-generator according to claim 1, wherein the electric current source connected to a stator magnetising winding of a first stator pole comprises, at least partially, the electrical pulses induced in the stator magnetising winding of a different second stator pole, the stator pole set configuration in relation to the rotor pole set configuration being such that the first stator pole is coming into register with a rotor pole as the second stator pole separates from its in-register position with a rotor pole.
5. A motor-generator according to claim 1, wherein the number of poles in a set of stator poles is different from the number of rotor poles in each rotor section.
6. A motor-generator according to claim 1, wherein the stator configuration provides pole pieces which are common to both rotor sections in the sense that when stator and rotor poles are in-register the stator pole pieces constitute bridging members for magnetic flux closure in a magnetic circuit including that of the rotor magnetisation means disposed between the two rotor sections.
7. A motor-generator according to claim 6, wherein the number of poles in a set of stator poles and the number of rotor poles in each section do not share a common integer factor and the number of rotor poles in one rotor section is the same as that in the other rotor section.
8. A motor-generator according to claim 7, wherein the number of poles in a stator set and the number of poles in a rotor section differs by one and the pole faces are of sufficient angular width to assure that the magnetic flux produced by the rotor magnetisation means can find a circuital magnetic flux closure route through the bridging path of a stator pole and through corresponding rotor poles for any angular position of the rotor.
9. A motor-generator according to claim 8, wherein each rotor section comprises seven poles.
10. A motor-generator according to claim 7, wherein there are N rotor poles in each rotor section and each has an angular width that is $180/N$ degree of angle.
11. A motor-generator according to claim 7, wherein the stator pole faces have an angular width that is no greater than half the angular width of a rotor pole.
12. A motor-generator according to claim 1, wherein the rotor sections comprise circular steel laminations in which the rotor poles are formed as large teeth at the perimeter, and the rotor magnetisation means comprise a magnetic core structure the end faces of which abut two assemblies of such laminations forming the two rotor sections.
13. A motor-generator according to claim 1 in which the rotor magnetisation means comprises at least one permanent magnet located with its polarisation axis parallel with the rotor axis.
14. A motor-generator according to claim 13, wherein an apertured metal disc that is of a non-magnetisable substance is mounted on a rotor shaft and positioned intermediate the two rotor sections and each aperture provides location for a permanent magnet, whereby the centrifugal forces acting on the permanent magnet as the rotor rotates are absorbed by the stresses set up in the disc.
15. A motor-generator according to claim 1, having a rotor mounted on a shaft that is of a non-magnetisable substance, whereby to minimise magnetic leakage from the rotor magnetising means.
16. An electrodynamic motor-generator machine comprising a stator configured to provide a set of stator poles, a corresponding set of magnetising windings mounted on the stator pole set, a rotor having two sections each of which has a set of salient pole pieces, the rotor sections being axially spaced along the axis of rotation of the

rotor, rotor magnetisation means incorporated in the rotor structure and arranged to polarise the rotor poles, whereby the pole faces of one rotor section all have a north polarity and the pole faces of the other rotor section all have a south polarity and electric circuit connections between an electric current source and the stator magnetising windings arranged to regulate the operation of the machine by admitting current pulses for a duration determined according to the angular position of the rotor, which pulses have a direction tending to oppose the polarisation induced in the stator by the rotor polarisation as stator and rotor poles separate from an in-register position, whereby the action of the rotor magnetisation means provides a reluctance motor drive force to bring stator and rotor poles into register and the action of the stator magnetisation windings opposes the counterpart reluctance braking effect as the poles separate.

17. A motor-generator according to claim 16, wherein the electric current source connected to a stator magnetising winding of a first stator pole comprises, at least partially, the electrical pulses induced in the stator magnetising winding of a different second stator pole, the stator pole set configuration in relation to the rotor pole set configuration being such that the first stator pole is coming into register with a rotor pole as the second stator pole separates from its in-register position with a rotor pole.

Amendments to the claims have been filed as follows 1. An electrodynamic motor-generator machine comprising a stator configured to provide a set of stator poles, a corresponding set of magnetising windings mounted on the stator pole set, a rotor having two sections each of which has a set of salient pole pieces, the rotor sections being axially spaced along the axis of rotation of the rotor, rotor magnetisation means disposed between the two rotor sections arranged to produce a unidirectional magnetic field which magnetically polarises the rotor poles, whereby the pole faces of one rotor section all have a north polarity and the pole faces of the other rotor section all have a south polarity and electric circuit connections between an electric current source and the stator magnetising windings arranged to regulate the operation of the machine by admitting current pulses for a duration determined according to the angular position of the rotor, which pulses have a direction tending to oppose the polarisation induced in the stator by the rotor polarisation as stator and rotor poles separate from an in-register position, whereby the action of the rotor magnetisation means provides a reluctance motor drive force to bring stator and rotor poles into register and the action of the stator magnetisation windings opposes the counterpart reluctance braking effect as the poles separate, the machine being characterised in that the stator comprises separate ferromagnetic bridging members mounted parallel with the rotor axis, the ends of which constitute stator poles and the core sections of which provide closure paths operative when the stator and rotor poles are in register to confine magnetic flux developed by the rotor magnetisation means to a stator flux path of restricted cross-section disposed anti-parallel with the unidirectional magnetic field polarisation axis of the rotor magnetising means 2. A motor-generator according to claim 1, wherein the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide demagnetisation of the stator poles as the stator and rotor poles separate from an in-register position.

3. A motor-generator according to claim 1, wherein the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide a reversal of magnetic flux direction in the stator poles as the stator and rotor poles separate from an in-register position, whereby to draw on power supplied from the electric current source to provide additional forward drive torque.
4. A motor-generator according to claim 1, wherein the electric current source connected to a stator magnetising winding of a first stator pole comprises, at least partially, the electrical pulses induced in the stator magnetising winding of a different second stator pole, the stator pole set configuration in relation to the rotor pole set configuration being such that the first stator pole is coming into register with a rotor pole as the second stator pole separates from its in-register position with a rotor pole.
5. A motor-generator according to claim 1, wherein the number of poles in a set of stator poles is different from the number of rotor poles in each rotor section.
6. A motor-generator according to claim 1, wherein the stator configuration provides pole pieces which are common to both rotor sections in the sense that when stator and rotor poles are in-register the stator pole pieces constitute bridging members for magnetic flux closure in a magnetic circuit including that of the rotor magnetisation means disposed between the two rotor sections.
7. A motor-generator according to claim 6, wherein the number of poles in a set of stator poles and the number of rotor poles in each section do not share a common integer factor and the number of rotor poles in one rotor section is the same as that in the other rotor section.

**SELF-SUSTAINING ELECTRIC POWER GENERATOR UTILISING ELECTRONS
OF LOW INERTIAL MASS TO MAGNIFY INDUCTIVE ENERGY**

This patent application shows a very neat, self-powered electrical generator with a theoretical output of anything up to a COP of 59 when using cadmium selenide. The discussion of the theoretical aspects of the design includes a large amount of historical information and it covers the origin of the "law" of Conservation of Energy which, in spite of being incorrect, has been for decades, a major obstacle to the scientific development of free-energy devices.

Filed: 6th March 2006

Assignee: Levitronics, Inc.

Provisional application No. 60/697,729 filed on 8th July 2005

ABSTRACT

Electrical oscillations in a metallic "sending coil" radiate inductive photons toward one or more "energy-magnifying coils" comprised of a photoconductor or doped semiconductor coating a metallic conductor, or comprised of a superconductor. Electrons of low inertial mass in the energy-magnifying coil(s) receive from the sending coil, a transverse force having no in-line backforce, which exempts this force from the energy-conservation rule. The low-mass electrons in the energy-magnifying coil(s) receive increased acceleration proportional to normal electron mass divided by the lesser mass. Secondarily radiated inductive-photon energy is magnified proportionally to the electrons' greater acceleration, squared, e.g., the inductive-energy-magnification factor of CdSe photoelectrons with 0.13 x normal electron mass is 59 times. Magnified inductive-photon energy from the energy-magnifying coil(s) induces oscillating electric energy in one or more metallic "output coil(s)". The electric energy output exceeds the energy input if more of the magnified photon induction energy is directed toward the output coil(s) than is directed as a counter force to the sending coil. After an external energy source initiates the oscillations, feedback from the generated surplus energy makes the device a self-sustaining generator of electric power for useful purposes.

CROSS REFERENCE TO RELATED APPLICATION

This application corresponds to, and claims the benefit under 35 U.S.C. 119(e), of U.S. provisional application No. 60/697,729, filed on 8th July 2005, incorporated herein by reference in its entirety.

FIELD

This disclosure introduces a technical field in which practical electrical energy is created in accordance with the overlooked exception to the energy-conservation rule that Herman von Helmholtz described in his 1847 doctrine on energy conservation: "If . . . bodies possess forces which depend upon time and velocity, or which act in directions other than lines which unite each pair of material points, . . . then combinations of such bodies are possible in which force may be either lost or gained as infinitum". A transverse inductive force qualifies for Helmholtz's ad infinitum rule, but this force is not sufficient of itself to cause a greater energy output than input when applied to electrons of normal mass due to their unique charge-to-mass ratio. However, the increased acceleration of conduction electrons of less-than-normal inertial mass, as occurs in photoconductors, doped semiconductors, and superconductors, is proportional to the normal electron mass divided by the low electron mass, and the magnification of harnessable inductive energy is proportional to the square of the greater relative acceleration.

BACKGROUND

Magnetic force also satisfies Helmholtz's exemption to the energy-conservation rule because magnetic force is transverse to the force that causes it, and magnetic force is determined by the "relative velocity" (i.e. perpendicular to the connecting line) between electric charges. Magnification of magnetic force and energy was demonstrated by E. Leimer (1915) in the coil of a speaker phone and in the coil of a galvanometer when he irradiated a radio antenna-wire with radium. A 10 milligram, linear radium source produced a measured 2.6 fold increase in electrical current in the antenna wire in comparing inaudible radio reception without radium to audible reception with radium. This represented a $(2.6)^2 = 7$ times increase in electrical energy flowing through the

respective wire coils. The possibility of this enhanced reception being attributed to a person's body holding the unit of radium to the wire was eliminated by Leimer's additional observation that whenever the orientation of the small radium unit was changed to approximately 30 degrees relative to the wire, the energy enhancement ceased.

Applicant has deduced that Leimer's energy magnification was most likely due to low-mass electrons that were liberated and made conductive in the antenna by alpha radiation, which allowed these special electrons to be given a greater than normal acceleration by the received radio broadcast photons. Applicant has further deduced that such low-mass electrons must have originated in a thin-film coating of cupric oxide (CuO) on the antenna wire. CuO is a dull black polycrystalline semiconducting compound that develops in situ on copper and bronze wire in the course of annealing the wire in the presence of air. Such CuO coatings have been observed by Applicant on historical laboratory wire at the Science Museum at Oxford University, U.K. and on copper house wire of that era in the U.S., indicating that CuO coatings were commonplace. In later years, annealing has taken place under conditions that prevent most oxidation. This is followed by acid treatment to remove any remaining oxides, leaving shiny wire.

The same year that the English translation of Leimer's paper appeared in *Scientific American*, 16-year old Alfred M. Hubbard of Seattle, Washington, reportedly invented a fuelless generator, which he later admitted, employed radium. Applicant interprets this as implying that Leimer's energy-magnification was utilised by Hubbard with feedback to make it self-sustaining. Three years later, Hubbard publicly demonstrated a relatively advanced fuelless generator that illuminated a 20-watt incandescent bulb (Anon. 1919a). A reputable physics professor from Seattle College, who was intimately familiar with Hubbard's device (but not at liberty to disclose its construction details), vouched for the integrity of the fuelless generator and declared that it was not a storage device, but he did not know why it worked (Anon. 1919b). Because Hubbard initially had no financial means of his own, it is likely that the professor had provided Hubbard with the use of the expensive radium initially and thereby witnessed the inventing process in his own laboratory.

Newspaper photos (Anon. 1920a) of a more impressive demonstration of Hubbard's fuelless generator, show a device described as 14 inches (36 cm) long and 11 inches (28 cm) in diameter, connected by four heavy electrical cables to a 35 horsepower (26 kW) electric motor. The motor reportedly propelled an 18-foot open launch around a lake at a speed of 8 to 10 knots (Anon. 1920b). The event was witnessed by a cautious news reporter who claims to have checked thoroughly for any wires that might have been connected to hidden batteries, by lifting the device and motor from the boat. Radioactive-decay energy can be eliminated as the main power source because about 10^8 times more radium than the entire world's supply would have been needed to equal Hubbard's reported electric energy output of 330 amperes and 124 volts.

Lester J. Hendershott of Pittsburgh, Pa., reportedly demonstrated a fuelless generator in 1928 that was claimed by Hubbard to be a copy of his own device (1928h). The president of Stout Air services, William B. Stout, who also designed the Ford Trimotor aeroplane, reported (1928b): "The demonstration was very impressive. It was actually uncanny.... The small model appeared to operate exactly as Hendershot explained it did". Also reportedly attesting to the operability of Hendershott's fuelless generator were Colonel Charles A. Lindbergh and Major Thomas Lanphier of the U.S. Air Corps (1928a, et seq.), and Lanphier's troops reportedly assembled a working model of his device.

To the Applicant's best knowledge, the only depiction that was made public of the interior components of any of these reported generators consists of a sketchy drawing (Bermann 1928h) of Hubbard's apparatus similar in size to the device shown in his 1919 demonstration. It depicts a complex set of parallel coils measuring 6 inches (15 cm) in length and 4.5 inches (11.4 cm) in overall diameter. Four leads of insulated wire, with the insulation peeled back, are shown coming out of the end of the device. What those four wires were connected to internally was not shown. Hubbard's description of the internal arrangement of coils in the device generally matches the drawing (Anon. 1920a): "It is made up of a group of eight electromagnets, each with primary and secondary windings of copper wire, which are arranged around a large steel core. The core likewise has a single winding. About the entire group of cells is a secondary winding". Nothing was reported or depicted about how components functioned with each other, or how much radium was used and where the radium was positioned. The only connectors visible on the drawing were between the outer windings of the eight electromagnet coils. These connectors show that the direction of the windings alternated between clockwise and counterclockwise on adjacent coils, so that the polarity of each electromagnet would have been opposite to that of its adjacent neighbours.

If the Hubbard and Hendershot devices actually operated as reported, they apparently never attained acceptance or commercial success. Assuming the devices actually worked, their lack of success may have been largely financially or supply based, or both, compounded with scepticism from believers in the energy-conservation doctrine. How much radium was employed by Hubbard in his larger generator can only be guessed at, but assuming a typical laboratory radium needle containing 10 milligrams of radium was used, that amount would have cost \$900 in 1920, dropping to \$500 in 1929. That much radium in a fuelless generator would have cost as much as an inexpensive automobile in the 1920s. Possibly much more radium was used than 10 milligrams.

In 1922, when the Radium Company of America of Pittsburgh, Pa., reportedly discontinued its work with Hubbard on his invention (1928h), the entire world's supply of radium was only about 250 grams. With the extreme

assumption that only 1 milligram of radium was needed per generator, less than 10% of a single year's production of autos in the US in the mid-1920s could have been supplied with such generators. Apparently Hendershott had tried to revive the technology by showing that the fuelless generator could extend the range of air flight indefinitely, but his technology never attracted a sponsor from any private, public or philanthropic entity.

U.S. Pat. No. 4,835,433 to Brown, superficially resembles the drawing of Hubbard's device. Brown's device appears to have the same number and essentially the same general arrangement of wire coils as Hubbard's generator, as nearly as can be understood from the newspaper articles depicting that device. Apparently, no information concerning either the Hubbard or Hendershot devices was considered during the prosecution of the '433 patent. Brown discusses the conversion of energy of radioactive decay products, principally alpha emissions, to electrical energy by amplifying electrical oscillations in a high-Q L-C circuit irradiated by radioactive materials. "During the absorption process, each alpha particle will collide with one or more atoms in the conductor, knocking electrons from their orbits and imparting some kinetic energy to the electrons in the conductor, thereby increasing its conductivity". (Col. 3, Line 68 to Col. 4, line 5). No claim was made by Brown, that the device employed a semiconductor or photoconductor that could have provided low-mass electrons for energy magnification.

Brown claimed an output of 23 amps at 400 volts, which is vastly greater than all the decay energy represented by his reported radioactive content of 1 milligram of radium that was surrounded by weakly radioactive uranium rods and thorium powder. Powered thorium is highly pyrophoric, so it is typically sealed in a nitrogen atmosphere to prevent spontaneous combustion. In his device, Brown reportedly confined the thorium in cardboard without any mention of sealing out air. This condition would have invited a meltdown that could have been interpreted as massive out-of-control electrical production.

To the best of the Applicant's knowledge, no person other than the Applicant has ever indicated that the presence of cupric oxide on their wires could have provided energy magnification. If Hubbard's device actually did work, certain characteristics of its design are unexplainable by the Applicant, namely the use of four rather than two large electrical cables to connect his device to an electrical motor, and the use of alternating polarity instead of single-direction polarity in the orientation of the multiple coils surrounding a central coil. Applicant therefore believes that the specification herein sets forth original configurations of electrical-energy generators that have no known precedent.

SUMMARY

To address the needs for electrical generators which are capable of self-generating substantial amounts of electrical power in various environments, and which are portable as well as stationary, apparatus and methods are provided for magnifying an electrical input, and (with feedback) for generating usable electrical power indefinitely without fuel or other external energy source, except for starting. The apparatus utilizes electrons of low effective mass, which receive greater acceleration than normal electrons in an amount that is inversely proportional to the effective mass. Applicant has determined that effective mass is the same as the electron's true inertial mass. The photon energy that is radiated when an electron is accelerated is proportional to the square of the acceleration, so the increase in radiated photon energy from an accelerated low-mass electron over the energy from a normal electron is equal to the inverse square of the effective mass, e.g. the calculated energy magnification provided by photoconducting electrons in cadmium selenide, with an electron effective mass of 0.13, is 59 times. The use of a transverse force, that lacks a direct back-force, to accelerate low-mass electrons in an oscillating manner, circumvents any equal-and-opposite force that would invoke the application of the energy-conservation law of kinetics and thermodynamics.

The various embodiments of the apparatus, which are configured either to continuously magnify an input of oscillating electric energy, or to serve as a self-sustaining electric generator, employ three principal components:

At least one sending coil

At least one energy-magnification coil, comprising a material that produces , in a "condition" low-mass electrons, and

At least one output coil.

It is desirable that the apparatus also includes a means for establishing the condition with respect to the energy-magnifying coil(s). Except where otherwise indicated in the remainder of this text, where the number of coils of a particular type is referred to in the singular, it will be understood that a plurality of coils of the respective type can alternatively be utilised.

Electrical oscillation in the sending coil, which is comprised of a metallic conductor, causes radiation of inductive photons from the sending coil. The energy-magnifying coil is situated in a position relative to the sending coil so as to receive inductive photons from the sending coil. The inductive photons radiating from electrical oscillations in the sending coil, convey a transverse force to the low-mass electrons in the energy-magnification coil with no

back-force on the sending coil. The greater-than-normal accelerations which are produced in the low-mass electrons of the energy-magnifying coil, produce greater irradiation energy of inductive photons than normal.

The output coil is positioned so as to receive the magnified inductive-photon energy from the energy-magnifying coil. The inductive-photon energy received by the output coil, which is comprised of a metallic conductor, is converted into an oscillating electrical current of normal electrons. In order for the electrical output to exceed the electrical input, the output coil is situated in such a manner that it receives more of the magnified inductive-photon energy than that which is directed back against the sending coil to act as a back-force. This "energy leverage" causes the electrical energy output to exceed the electrical energy input.

By way of example, the energy-magnifying coil can comprise a superconducting material, wherein the "condition" is a temperature (e.g. a cryogenic temperature) at which the superconducting material exhibits superconducting behaviour characterised by production of low-mass electrons.

By way of another example, the energy-magnifying coil can comprise a photoconductive material, wherein the "condition" is a situation in which the photoconductive material is illuminated by a wavelength of photon radiation sufficient to cause the photoconductive material of the energy-magnifying coil to produce conduction electrons having low effective mass. In this latter example, the means for establishing the condition can comprise a photoconductor exciter (e.g. one or more LEDs) situated and configured to illuminate the photoconductive material of the energy-magnifying coil with the wavelength of photon radiation.

By way of yet another example, the "condition" is the presence of a particular dopant in a semiconductor that provides a low-mass electron as a charge carrier. Also, by way of example, the energy-magnifying coil can comprise a semiconductive element or compound that has been doped with a particular element or compound that makes it conductive of low-mass electrons without illumination by photon radiation other than by ambient photons.

Various apparatus embodiments comprise different respective numbers and arrangements of the principal components. The various embodiments additionally can comprise one or more of circuitry, energisers, shielding and other components to fulfill the object of providing a self-sustaining source of electrical power for useful purposes.

Also provided, are methods for generating an electrical current. In an embodiment of such a method, a first coil is energised with an electrical oscillation sufficient to cause the first coil to radiate inductive photons. At least some of the radiated inductive photons from the first coil are received by a second coil, called "the energy-magnifying coil", comprising a material that produces low-mass electrons. The received inductive photons impart respective transverse forces to the low-mass electrons that cause the low-mass electrons to experience accelerations in the material which are greater than accelerations that otherwise would be experienced by normal free electrons experiencing the transverse forces.

Conduction of the accelerated low-mass electrons in the second coil, causes the second coil to produce a magnified inductive force. The magnified inductive force is received by a third coil which causes the third coil to produce an oscillating electrical output of normal conduction electrons which has greater energy than the initial oscillation. A portion of the oscillating electrical output is directed as feed-back from the third coil to the sending coil, so as to provide the electrical oscillation to the sending coil. This portion of the oscillating electrical current directed to the sending coil, desirably is sufficient to cause self-sustaining generation of inductive photons by the first coil without the need for any external energy source. The surplus oscillating electrical output from the third coil can be directed to a work loop.

The method can further comprise the step of starting the energisation of the first coil to commence generation of the oscillating electrical output. This "starting" step can comprise momentarily exposing the first coil to an external oscillating inductive force or for example, to an external magnetic force which initiates an electrical pulse.

The foregoing and additional features and advantages of the invention will be more readily apparent from the following detailed description, which proceeds with reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1(A)

Fig.1A is a perspective view schematically depicting a sending coil in relationship to an energy-magnifying coil such that inductive photons from the sending coil, propagate to the energy-magnifying coil.

Fig. 1(B)

Fig.1B is a schematic end-view of the sending coil and energy-magnifying coil of **Fig.1A**, further depicting radiation of inductive photons from the sending coil and the respective directions of electron flow in the coils.

Fig. 1(C)

Fig.1C is a schematic end-view of the sending coil and energy-magnifying coil of **Fig.1A**, further depicting the production of inwardly-radiating and outwardly-radiating magnified inductive photons from the energy-magnifying coil.

Fig. 2(B)

Fig.3 is an electrical schematic diagram of a representative embodiment of a generating apparatus.

Fig.4 is a schematic end-view of a representative embodiment, comprising a centrally disposed sending coil surrounded by six energy-magnifying coils, each having an axis which is substantially parallel to the axis of the sending coil. A respective internal output coil is coaxially nested inside each energy-magnifying coil, and the energy-magnifying coils are arranged so as to capture substantially all the inductive photons radiating from the sending coil.

Fig.5 is a schematic end-view of the embodiment of **Fig.4**, further including an external output coil situated coaxially with the sending coil and configured to surround all six energy-magnifying coils so as to capture outwardly-radiating inductive photons from the energy-magnifying coils. Also depicted is the greater amount of magnified inductive-photon radiation that is received by the internal output coils and the external output coil in comparison to the lesser amount of inductive-photon radiation that is directed towards the sending coil to act as a back-force. Also shown are the arrays of LEDs used for exciting the energy-magnifying coils to become photoconductive.

Fig.6 is a perspective view of the embodiment of **Fig.4** and **Fig.5** but further depicting respective inter-coil connections for the energy-magnifying and internal output coils, as well as respective leads for the sending coil, internal output coils and external output coil.

Fig.7 is a head-end view schematically depicting exemplary current-flow directions in the sending coil, energy-magnifying coils, internal output coils, and external output coils, as well as in the various inter-coil connections of the embodiment of **Fig.4**.

Fig. 8

Fig.8 is a schematic end-view showing an embodiment of the manner in which inter-coil connections can be made between adjacent energy-magnifying coils.

Fig. 9(A)

Fig.9A is a schematic end-view depicting the coil configuration of an embodiment in which a sending coil and an internal output coil are nested inside an energy-magnifying coil, which in turn is nested inside an exterior output coil. A metallic separator, having a substantially parabolic shape, and being situated between the sending coil and the internal output coil, reflects some of the otherwise unused inductive-photon radiation to maximise the effective radiation received by the energy-magnifying coil. Also, the metallic shield prevents the internal output coil from receiving radiation sent from the sending coil.

Fig. 9(B)

Fig.9B is a schematic end-view of the coil configuration of **Fig.9A**, further depicting the metallic separator acting as a shield to restrict the back-force radiation reaching the sending coil while allowing the internal output coil to receive a substantial portion of the magnified radiation from the energy-magnifying coil. Also depicted is the greater amount of magnified inductive-photon radiation that is received by the internal output coil and the external output coil in comparison to the lesser amount that is received by the sending coil to act as a back-force.

Fig. 10(A)

Fig10A is a schematic end-view depicting the coil configuration of yet another embodiment that is similar in some respects to the embodiment of **Fig.4**, but also including respective ferromagnetic cores inside the sending coil and internal output coils. Also depicted is a metallic shield surrounding the entire apparatus.

Fig. 10(B)

Fig.10B is a schematic end-view of a sending coil of yet another embodiment in which a ferromagnetic sleeve is disposed coaxially around the sending coil.

DETAILED DESCRIPTION

General Technical Considerations

An understanding of how “infinite energy” mistakenly came to be rejected by the scientific community, clarifies the basis of this invention. The electrodynamic function described in the embodiments described below, conforms to Helmholtz’s alternate energy rule, which states that a force which is not in line with it’s causative force “may be lost or gained ad infinitum”. This rule was included in “Über die Erhaltung der Kraft” (“On the Conservation of Force”) that Hermann Helmholtz delivered to the Physical Society of Berlin in 1847. But, Helmholtz mistakenly believed that “all actions in nature are reducible to forces of attraction and repulsion, the intensity of the forces depending solely upon the distances between the points involved so it is impossible to obtain an unlimited amount of force capable of doing work as the result of any combination whatsoever of natural objects”.

Helmholtz refused to accept the idea that magnetic energy qualifies for ad infinitum status despite the fact that Ampere’s (1820) magnetic force on parallel straight conductors is obviously transverse to the direction of the electric currents rather than being in line with the currents. He omitted mention that the magnetic force in Ampere’s (1825) important invention, the solenoidal electromagnet, is caused by currents in the loops of his coils, which are transverse to the direction of magnetic force. Also, he failed to mention that Ampere considered the magnetic force of a permanent magnet to be caused by minute transverse circular currents, which are now recognised as electrons that spin and orbit transversely.

Helmholtz, who was educated as a military medical doctor without any formal study of physics, relied instead on an obsolete metaphysical explanation of magnetic force: “Magnetic attraction may be deduced completely from the assumption of two fluids which attract or repel in the inverse ratio of the square of their distance....It is known that the external effects of a magnet can always be represented by a certain distribution of the magnetic fluids on its surface”. Without departing from this belief in magnetic fluids, Helmholtz cited Wilhelm Weber’s (1846) similarly wrong interpretation that magnetic and inductive forces are directed in the same line as that between the moving electric charges which cause the forces.

Weber had thought that he could unify Coulombic, magnetic, and inductive forces in a single, simple equation, but Weber’s flawed magnetic-force term leads to the absurd conclusion that a steady current in a straight wire induces a steady electric current in a parallel wire. Also, a changing current does not induce an electromotive force in line with the current, as Weber’s equation showed. The induced force is offset instead, which becomes more apparent the further that two nested, coaxial coils are separated. What appears to be a directly opposing back-force is actually a reciprocal inductive force.

Helmholtz’s assertion that the total sum of the energy in the universe is a fixed amount that is immutable in quantity from eternity to eternity appealed to his young friends. But, the elder scientists of the Physical Society of Berlin declared his paper to be “fantastical speculation” and a “hazardous leap into very speculative metaphysics”, so it was rejected for publication in *Annalen der Physik*. Rather than accept this rejection constructively, Helmholtz found a printer willing to help him self-publish his work. Helmholtz headed the publication with a statement that his paper had been read before the Society, but he disingenuously withheld mention of its outright rejection. Unwary readers have since received the wrong impression that his universal energy-conservation rule had received the Society’s endorsement rather than its censure.

Helmholtz (1862, 1863) publicised his concept thus: “We have been led up to a universal natural law, which ... expresses a perfectly general and particularly characteristic property of all natural forces, and which ... is to be placed by the side of the laws of the unalterability of mass and the unalterability of the chemical elements”. Helmholtz (1881) declared that any force that did not conserve energy would be “in contradiction to Newton’s axiom, which established the equality of action and reaction for all natural forces” (sic). With this deceitful misrepresentation of Newton’s strictly mechanical principle, Helmholtz had craftily succeeded in commuting the profound respect for Newton’s laws to his unscientific doctrine. Subsequently, the Grand Cross was conferred on Helmholtz by the kings of Sweden and Italy and the President of the French Republic, and he was welcomed by the German Emperor into nobility with the title of “von” added to his name. These prestigious awards made his doctrine virtually unassailable in the scientific community.

Ampere’s principle of transverse magnetic attraction and repulsion between electric currents had been made into an equation for the magnetic force between moving electric charges by Carl Fredrick Gauss (written in 1835, published posthumously in 1865). The critical part of the Gauss equation shows, and modern physics texts agree, that magnetic force is transverse to the force that imparts a relative velocity (i.e. perpendicular to a connecting line) between charges. Lacking a direct back-force, a transverse magnetic force can produce a greater force than the force that causes it.

The only physicist to recognise in print, the profound significance of the work of Gauss, was James Clerk Maxwell (1873), who stated "(If Gauss's formula is correct), energy might be generated indefinitely in a finite system by physical means". Prepossessed with Helmholtz's "law", Maxwell chose not to believe Gauss's transverse magnetic-force equation and accepted Wilhelm Weber's (1846) erroneous in-line formula instead. Maxwell even admitted knowing of Gauss's (1845) rebuke of Weber for his mistaken direction of magnetic force as "a complete overthrow of Ampere's fundamental formula and the adoption of essential a different one".

In 1893, the critical part of Ampere's formula for magnetic force, which Weber and Maxwell rejected, and which Helmholtz had replaced with his contrary metaphysical explanation, was proposed for the basis for the international measure of electric current, the Ampere (or amp), to be defined in terms of the transverse magnetic force which the current produces. But Helmholtz's doctrine had become so impervious to facts that anyone who challenged this "law" faced defamation and ridicule.

The first recognition of unlimited energy came from Sir Joseph Larmor who reported in 1897, "A single ion e , describing an elliptic orbit under an attraction to a fixed centre ... must rapidly lose its energy by radiation ... but in the cases of steady motion, it is just this amount that is needed to maintain the permanency of motion in the aether". Apparently to mollify critics of his heretical concept, Larmor offered a half-hearted recantation in 1900: "The energy of orbital groups ... would be through time, sensibly dissipated by radiation, so that such groups could not be permanent".

In 1911, Rutherford found that an atom resembles a small solar system with negative ions moving like planets around a small, positively charged nucleus. These endlessly orbiting electrons were a source of the perpetual radiation that had aptly been described by Larmor, and these orbiting electrons were also Planck's (1911) "harmonic oscillators" which he used to explain Zero-point Energy (ZPE). ZPE was shown by the fact that helium remains liquid under atmospheric pressure at absolute zero, so that helium must be pressurised to become solid at that temperature. Planck believed that harmonic oscillators derived "dark energy" from the aether to sustain their oscillations, thereby admitting that an infinite source of energy exists. However, he assigned an occult origin to this infinite energy, rather than a conventional source that had not met with Helmholtz's approval.

Niels Bohr (1924) was bothered by the notion that radiation from an orbiting electron would quickly drain its energy so that the electron should spiral into the nucleus. Whittaker (1951) states, "Bohr and associates abandoned the principle ... that an atom which is emitting or absorbing radiation must be losing or gaining energy. In its place, they introduced the notion of virtual radiation, which was propagated in ... waves but which does not transmit energy or momentum". Subsequently, the entire scientific community dismissed Larmor radiation as a source of real energy because it failed to conform to Helmholtz's universally accepted doctrine.

Helmholtz's constraining idea that the vast amount of light and heat radiating from the many billions of stars in the universe can only come from previously stored energy, has led scientists to concur that fusion of pre-existing hydrogen to helium, supplies nearly all the energy that causes light and heat to radiate from the sun and other stars. If so, then the entire universe will become completely dark after the present hydrogen supply in stars is consumed in about 20 billion years. William A. Fowler (1965) believed that essentially all the hydrogen in the universe "emerged from the first few minutes of the early high-temperature, high-density stage of the expanding Universe, the so-called 'big bang' ...". Moreover, the background energy of the universe was thought by some to be "relic" radiation from the "Big Bang".

To accept the Big Bang idea that all the stars in the universe originated at the same time, it was necessary to disregard the fact that most stars are much younger or much older than the supposed age of the one-time event, which indicates that their energy must have come from a recurring source. The Big Bang is entirely dependent on the idea that the whole universe is expanding, which stemmed from the interpretation that Hubble's red-shift with distance from the light source, represents a Doppler shift of receding stars and galaxies. This expanding-universe interpretation was shattered by William G. Tifft (1976, 1977), who found that observed red-shifts are not spread randomly and smoothly over a range of values, as would be expected from the Doppler shifts of a vast number of receding stars and galaxies. Instead, the observed red-shifts all fall on evenly spaced, quantised values.

Moreover, Shpenkov and Kreidik (2002) determined that the radiation temperature corresponding to the fundamental period of the orbital electron motion in the hydrogen atom of 2.7289^0K matches the measured temperature of cosmic background radiation of 2.725^0K plus or minus 0.002^0K . This represents perpetual zero-level Larmor radiation from interstellar hydrogen atoms dispersed in the universe. So, Helmholtz's idea that "the energy in the universe is a fixed amount immutable in quantity from eternity to eternity" does not stand up to known facts.

The large aggregate quantity of heat-photons which is generated continually by Larmor radiation can account for the illumination of stars and for the enormous heat and pressure in active galactic centres. Based on the fact that photons exhibit momentum, photons must possess mass, because, as Newton explained, momentum is mass times velocity, which in this case is " c ". Consequently, the creation of photons by induction or by Larmor radiation, also creates new mass. The conditions that Fowler was seeking for hydrogen nucleosynthesis, are apparently being supplied indefinitely in active galaxies and possibly in the sun and other stars above a certain size. This invention utilises a similar unlimited energy source.

Another principle that is important to this specification, is that the transfer of energy by electrical induction was found by the Applicant to work in the same manner as the transfer of energy by broadcast and reception of oscillating radio signals. A transverse force is communicated in both cases, the force declines similarly with distance, and the effects of shielding and reflection are identical. Since radio signals are communicated by photons, Applicant considers that inductive force is also communicated by photons. The radiation of newly formed inductive photons results when an accelerated charge experiences a change in direction of acceleration. Inductive radiation occurs when the acceleration of electric charges is reversed, as in Rontgen's bremsstrahlung, in Hertz's linear oscillator (plus all other radio-broadcasting antennas), and in coils which carry an alternating current.

In a similar case, when electric charges move in a curving motion due to a continually changing centripetal acceleration, inductive photons are radiated steadily. This includes the radiation from electrons orbiting atomic nuclei (Larmor radiation) and from conduction electrons flowing in a wire coil, whether the current is steady or not. Circularly produced inductive photons induce a circular motion (diamagnetism) in mobile electrons located near the axis of the electron's circular movement.

In both the reverse-acceleration and centripetal-acceleration cases, inductive photons convey a force to mobile electrons that is transverse to the photon's propagation path. As Lapp and Andrews (1954) reported, "Low-energy photons produce photoelectrons at right angles to their path ...". This same right-angle force without a direct back-force, applies as well, to all conduction electrons which are accelerated by low-energy photons. Hence, inductive energy qualifies for exemption from the energy-conservation law by Helmholtz's same ad infinitum principle which exempts magnetic energy.

The transverse force that inductively produced photons delivered to mobile electrons, is opposite in direction to the simultaneous movement of the primary charge which produces the radiation. This is shown by Faraday's induced current opposite to the inducing current and by the diamagnetically-induced circular motion which, in a rotational sense, is opposite to the circular electron motion in the coil producing it. An oscillating flow of electrons within a loop of a wire coil, induces a force on the conduction electrons which is in the opposite direction in adjacent loops of the same wire. This results in self-induction.

Important to this specification is the realisation that the energy transmitted by photons is kinetic rather than electromagnetic. Inductively radiated photons of low energy, light rays and X-rays cannot be deflected by an electric or magnetic field due to the photons' neutral charge. Neither do neutral photons carry an electric or magnetic field with them. Photon radiation is produced by a change in the acceleration of an electric charge, so only in special cases does it have an electrokinetic origin which involves a magnetic force. To honour these facts, Applicant uses the term "electrokinetic spectrum" in place of "electromagnetic spectrum".

Another principle which is important to this specification is the realisation that, although the charge on the electron has a constant value under all conditions, the mass of an electron is not a fixed, unchanging amount. All free electrons, as in cathode rays, have exactly the same amount of mass at sub-relativistic velocities. This is called "normal" mass and is denoted by m_e . Free electrons have a unique charge to mass ratio that makes the magnetic force resulting from a sub-relativistic velocity imparted to such an electron, exactly equal to the energy input with "normal" electrons.

Also, when a normal electron is given a sub-relativistic acceleration, the inductive force it produces is equal to the force it receives. The mass of highly conductive electrons of metals is apparently very close to normal, but any very slight inductive-energy gains would be masked by inefficiencies. The ubiquity of free electrons and the conduction electrons of metals has led to the view that electron mass is a never-varying figure that would allow the energy conservation law to apply to magnetic energy and inductive energy.

Accurate determinations of electron mass in solid materials have been made possible by cyclotron resonance, which is also called diamagnetic resonance. The diamagnetic force produced by the steady flow of electrons in a wire coil, induces the mobile electrons of a semiconductor to move in a circular orbit of indefinite radius but at a definite angular frequency. This frequency is only related to the inductive force and the mass of the electron. At the same time, a repulsive magnetic force is developed by the relative velocity between the electron flow in the coil and the conduction electrons, causing the mobile electrons of the semiconductor to move in a helical path away from the coil rather than in planar circles. Only two measurements are needed to determine the mass of such an electron: the cyclotron frequency which resonates with the frequency of the electron's circular motion, and the strength of the inductive force, which is determined by the current and dimensions of the coil. Since the co-produced magnetic field is related to the same parameters, its measurement serves as a surrogate for inductive force.

Because the measured mass of conduction electrons in semiconductors is less than normal, a complicated explanation has been adopted to defend the constancy of electron mass in order to support Helmholtz's energy doctrine. An extra force is supposedly received from the vibrational lattice-wave energy of the crystal (in what would have to be an act of self-refrigeration) to make normal-mass electrons move faster than expected around a circular path, thereby giving the appearance that the electron has less mass than normal. In this explanation, the electron is considered to be a smeared-out wave rather than a particle, which is contradicted by the billiard-ball-

like recoil of an electron when it is bumped by a quantum of radiation, as described by Arthur Crompton and Samuel Allison (1935).

The fallacy that borrowed energy can provide a boost in velocity to an electron, is more apparent in the case of linear motion. The effective-mass theory considers that the greater linear velocity is caused by a boost given to normal-mass electrons by a "longitudinal wave" imparted by an externally applied force in the same direction as the electron motion. Since this longitudinal wave is also considered to have a source in crystal-lattice vibrations, the effective-mass theory relies on a reversal of entropy in violation of the second Law of Thermodynamics.

No reasonable contribution of direct directional energy can be invoked from any source to impart abnormally great velocity to the conduction electrons in semiconductors. So, the operation of apparatus embodiments described herein, relies on electrons having particle properties and on electrons having less-than-normal inertial mass without invoking any special forces. This is supported by Brennan's (1999) statement that "the complicated problem of an electron moving within a crystal under the interaction of a periodic but complicated potential, can be reduced to that of a simple free particle, but with a modified mass". The term "effective" is herein considered redundant in referring to truly inertial mass, but "effective mass" still has relevance in referring to the net movement of orbital vacancies or "holes" in the opposite direction of low-mass electrons.

By $F = ma$, a low-mass electron receives greater acceleration and greater velocity from a given force than an electron of normal mass. The velocity and kinetic energy imparted to an electrically charged body by a force, are determined by the electric charge without regard to the body's mass. Having a smaller amount of mass, allows a body to attain a greater velocity with any given force. Hence, the magnetic force produced by the charge at this higher velocity will be greater than it would normally be for that same amount of force. This allows low-mass electrons to produce a magnetic force that is greater than the applied force.

Also, the amount of inductive radiation energy from accelerated electrons is related to an electron's charge without regard to its mass. The energy of inductive radiation increases with the square of the electron's acceleration according to Larmor's (1900) equation, while the acceleration is inversely proportional to the lesser electron mass relative to normal electron mass. Therefore, the greater-than-normal acceleration of low-mass electrons, allows the re-radiation of magnified inductive-photon energy at a magnification factor which is proportional to the inverse square of the electron's mass, e.g., the inductive-energy magnification factor of cadmium selenide photoelectrons with 0.13 of the normal electron mass is $(0.13)^2$ which is 59 times.

Electrons appear to acquire or shed mass from photons in order to fit the constraints of particular orbits around nuclei, because each orbit dictates a very specific electron mass. In metals, where the conduction electrons seem to move as would a gas, one might think that they would assume the normal mass of free electrons. But the largest mean free path of electrons in the most conductive metals is reportedly about 100 atomic spacings between collisions (Pops, 1997), so the conduction electrons apparently fall back into orbit from time to time and thereby regain their metal-specific mass values.

As conduction electrons pass from one metal type to another, they either lose or gain heat-photons to adjust their mass to different orbital constraints. In a circuit comprising two different metallic conductors placed in series contact with each other, the flow of conduction electrons in one direction will cause the emission of heat-photons at the junction, while an electron flow in the reverse direction causes cooling as the result of ambient heat-photons being absorbed by the conduction electrons at the junction (Peltier cooling effect). When a metal is joined with a semiconductor whose conductive electrons have much lower mass than in metals, much greater heating or cooling occurs at their junction.

John Bardeen (1941) reported that the (effective) mass of superconducting electrons in low-temperature superconductors is only 10^{-4} as great as the mass of normal electrons. This is demonstrated when superconducting electrons are accelerated to a much higher circular velocity than normal in diamagnetically induced eddy currents, which results in enormous magnetic forces which are capable of levitating heavy magnetic objects. Electrons with 10^{-4} times normal mass are apparently devoid, (or nearly devoid) of included photon mass, so normal electrons are deduced to possess about 10^4 times more included photon mass than the bare electron's own mass.

The means by which photon mass may be incorporated within, or ejected from electrons, can be deduced from known information. Based on the Thompson scattering cross-section, the classical radius of a normal electron is 2×10^{-15} cm. If the electron has uniform charge throughout a sphere of that radius, the peripheral velocity would greatly exceed the velocity of light in order to provide the observed magnetic moment. Dehmelt (1989) determined that the radius of the spinning charge which creates an electron's magnetism, is approximately 10^{-20} cm. This apparent incongruity can be explained if the electron is considered to be a hollow shell (which is commensurate with the bare electron's tiny mass in comparison to the very large radius) and if the negative charge of the shell is not the source of the magnetic moment.

It has long been known that a photon can be split into a negative ion (electron) and a positive ion (positron), each having the same amount of charge but of opposite sign. Electrons and positrons can recombine into electrically neutral photons, so it is apparent that photons are composed of a positive and a negative ion. Two

ions spinning around each other could produce the photon's wave nature. The only size of photon ion that can exist as a separate entity has a charge of exactly plus one or minus one, whereas the ions can have a very much larger or very much smaller charge and mass when combined in photons, as long as the two ions are equal in charge and mass. Combined in a photon, the two ions are apparently attracted together so strongly that their individual volumes are very much smaller than as separate entities.

When a dipole photon enters an electron shell, its negative-ion portion is expected to be forced towards the shell's centre by Coulombic repulsion, while the photon's positive ion would be attracted by the negative charge of the shell equally in all directions. The negative photon ions would likely merge into a single body at the electron's centre, while the positive-ion portion would orbit around the centralised negative ion to retain the photon's angular momentum. The high peripheral velocity of this orbiting photon mass would enable portions of photon material to spin off and exit the electron shell at the same velocity at which they entered the electron, i.e., the speed of light. The orbiting of the positive photon charge at Dehmelt's small radius, most likely accounts for the magnetic moment that is observed in electrons of normal mass.

Liberated low-mass conduction electrons within intrinsic semiconductors (which are also photoconductors by their nature) and within doped semiconductors, are mostly protected against acquiring mass from ambient-heat photons by the heat-insulative properties of the semiconductors. In contrast, low-mass electrons injected into heat-conducting metals, rapidly acquire mass from ambient-heat photons by the existence of cryogenic conditions, but they are vulnerable to internal heat-photons created by excessive induction.

Conduction electrons of metals, typically move as a group at drift velocities of less than one millimetre per second, although the velocity of the electrical effects approaches the velocity of light. (Photons are probably involved in the movement of electrical energy in metallic conductors.) In contrast, conductive low-mass electrons can move individually at great velocities in superconductors and semiconductors. Brennan (1999, p. 631) reports the drift velocity of a particular electron moving in a semiconductor, to be one micrometer in about 10 picoseconds, which is equivalent to 100 kilometers per second.

The concentration of the conduction electrons in metals is the same as the number of atoms, whereas in semiconductors, the mobile low-mass electrons which are free to move, can vary greatly with the amount of certain photon radiation received. Since the magnitude of an electric current is a summation of the number of electrons involved, times their respective drift velocities, the current developed by a small ensemble of photoconducting electrons moving at high speed, can exceed the current of a much greater number of conduction electrons moving at a very low speed in a metal.

A general feature of intrinsic semiconductors is that they become photoconductive in proportion to the amount of bombardment by some particular electron-liberating frequency (or band of frequencies) of photon energy, up to some limit. The amount of bombardment by the particular wavelength (or, equivalently, the frequency), increases along with all other photon wavelengths as the ambient temperature rises, that is, as the area under Planck's black-body radiation curve increases. Consequently, the conductivity of semiconductors continues to increase with temperature, while the conductivity drops to almost zero at low temperature unless superconductivity occurs.

A single high-energy alpha particle can liberate a great number of low-mass electrons in a thin-film semiconductor, as Leimer's (1915) energy-magnifying experiment appears to show. Leimer's alpha radiation was situated near the distant end of a suspended antenna wire of unreported length, when he experienced the maximum magnetic energy increase in the coil of the ammeter in the receiver. The low-mass electrons had to have travelled the entire length of the suspended antenna and the connecting line to his receiving apparatus without encountering any trapping holes. Assuming these electrons traversed a distance of 1 to 10 metres in less than one half-cycle of the radio frequency, (that is, less than 4 microseconds at 128 kHz) at which time the direction of the low-mass electron would have been reversed, this would be equivalent to velocities of 25 to 250 km/sec.

A great number of superconducting electrons can be set in motion by inductive photon radiation. In contrast, inductive photon radiation can pass mostly through photoconductors that have low concentrations of mobile, low-mass electrons. Applicant's interpretation of Leimer's experiment is that the liberated low-mass electrons of the semiconductor coating of the antenna wire, were not directly accelerated by the inductive photons of the radio signal, but rather were accelerated to high velocities by an oscillating electric field created in the metallic wire by the radio photons.

A review of an experiment performed by File and Mills (1963), shows that the very low mass of superconducting electrons is responsible for causing supercurrents to differ from normal electric currents. A superconducting solenoidal coil (comprising a Nb-25% Zr alloy wire below 4.3⁰ K.) with the terminals spot-welded together to make a continuous conductor, was employed. Extremely slow declines of induced supercurrents were observed, which can be attributed to an enormous increase in the coil's self-induction. Because a supercurrent approaches its maximum charge asymptotically when discharging, a convenient measure of the coil's charging or discharging rate is the "time-constant". The time-constant has the same value for both charging and discharging, and it is defined as (a) the time needed for charging the coil to 63% of the maximum amount of current inducible in the coil by a given diamagnetic force, or (b) the time needed to discharge 63% of the coil's induced current.

In normal conductors, the inductive time-constant is calculated by the inductance of the coil, divided by the resistance of the coil. By use of an empirical equation, the inductance of the coil in its non-superconducting state is calculated to be 0.34 Henry, based on a double-layered solenoid of 384 turns that measured 4 inches (10 cm) diameter and 10 inches (25 cm) long. The resistance of the 0.020 inch (0.51 mm) diameter wire at a temperature of 5⁰ K. (just above T_c) is estimated by using data for Zr alone, to be 4 x 10² ohms. (Resistivity data were not available for Nb or the subject alloy). Under non-superconducting conditions, the time-constant for charging and discharging this coil is thereby calculated to be approximately 8 x 10⁻⁵ sec.

The time it took to charge up a supercurrent in the coil in the experiment was not reported. But, based on the reported 50 re-energisings and magnetic determinations performed in 200 hours, the measured charging time in the superconducting state is computed to be no more than 4 hours on average.

Using Bardeen's (1941) formula of m is approximately equal to m_e times 10⁻⁴ for the order of magnitude of the low T_c superconducting electron's mass, and using Larmor's equation (1900) which relates inductive radiation power to the square of the acceleration of the charge, the inductance of the coil is expected to increase by (10⁻⁴)² = 10⁻⁸ times in the superconducting state. Thus, the calculated increase in the time-constant of charging up the supercurrent is 8 x 10⁻⁵ x 10⁸ which equals 8 x 10³ seconds, or 2.2 hours, which is the same order of magnitude as the maximum actual charging time. The self-induction increased by that amount because the low-mass electrons are accelerated 10⁴ times faster.

In the case of discharging, the time constant of the supercurrent was projected by File and Mills from measured declines observed over periods of 21 and 37 days. The projections of the two 63% declines agreed closely at 4 x 10¹² seconds (= 1.3 x 10⁵ years). Therefore, the time-constant of supercurrent discharge, based on projecting actual measurements, had increased by 5 x 10¹⁶ times over the time-constant for electrons of normal mass.
